Perhaps because utilitarians were so influential in the development of classical economics, the hedonistic interpretation of utility was also widely accepted by economists prior to the 'ordinalist revolution' of the 1930s and 1940s. Classical economists were preoccupied with the production and distribution of material wealth, however, and so tended to focus their attention on the kind of utilities embodied in material objects susceptible to accumulation. As used by Mill (1965: pp. 48–54), for example, the term 'productive labor' is confined to those types of actions that produce utilities embodied in material objects. Actions are classed as 'unproductive labor' (however useful to society) to the extent that they produce the other two kinds of utilities. Moreover, 'productive consumption' (i.e., investment) includes consumption by productive laborers of things which are necessary to maintain and increase their own health, strength, capacities of work, or population. But it does not include any consumption by unproductive laborers (those who do not produce material wealth) or consumption of luxuries by the productive themselves (however pleasing these forms of consumption are to the community). In short, although they did not deny that other kinds of utilities existed, economists in the classical and early neoclassical tradition (from Smith and Ricardo to Marshall and Pigou) tended to identify utility with material welfare and to be especially concerned about the needs of those members of the community who produced the kind of utilities embodied in material wealth.

In the post–Second World War period, utilitarian ethics have declined in influence and hedonistic conceptions of utility have largely been abandoned by economists and philosophers. Whereas philosophers (including utilitarians) have typically gone on to identify utility with some nonhedonistic idea of welfare, however, economists have generally adopted the technical idea of utility in its purely ordinalist form – utility is merely a convenient mathematical

tool for representing interpersonally noncomparable preference orderings (*see* Rational Choice Explanation: Philosophical Aspects). It is not obvious that philosophers should follow economists in viewing utility as a merely technical term, distinct from welfare. (For a controversial argument that this shift in the meaning of utility within economics – the product of the 'ordinalist revolution' – does not imply 'progress' because it has involved 'losses in understanding human welfare,' in particular, 'material welfare,' including any person's objective material needs; see Cooter and Rappoport, 1984. Further relevant discussion is given by Bruni and Sugden (2007).) But perhaps they should, without necessarily accepting the narrow restriction to pure ordinalism. Even so, it would be incorrect to conclude that because technical utility values are distinct from, and can conflict with, substantive welfare values, there is some inescapable contradiction between utility in the technical sense and welfare. This leads to a third reason for caution in insisting on a complete divorce between utility and welfare, to wit, the technical idea of utility may remain a formal aspect of any adequate conception of welfare if judgments about welfare are a species of preferences that can be represented by utility functions. In that case, technical utility, as a formal component of the idea of good, could be seen as a vestige of earlier utility concepts that identified utility with welfare.

Whether or not judgments about welfare can be represented by utility functions, the question remains: what are such judgments about?

Conceptions of Welfare

At least four different conceptions of welfare continue to be debated in the literature.

Welfare as Pleasure

Although currently out of favor, hedonistic conceptions have not vanished entirely and may be making a comeback (see, e.g., Kahneman et al., 1997; Kahneman, 1999; Kahneman and Sugden, 2005). Hedonism is typically dismissed as crude and naive, however, both as a psychology and as a theory of welfare. Expectation of pleasure including relief from pain is not the sole motivational force in human nature, it is said, and human good involves myriad things other than pleasure. No rational and moral person would be happy, for example, if his life consisted solely of a stream of supreme pleasures guaranteed by artificial means.

Perhaps such arguments are decisive against some versions of hedonism. But, as already discussed, the classical hedonism of Bentham, Mill and others does not deny that many things such as money and virtue are means to pleasure which can also become valued as ends-in-themselves, in which case they are seen as concrete ingredients of the idea of happiness. Classical hedonism is not a purely subjective doctrine. It insists that some kinds of pleasures are embodied in material objects and human qualities, and can only be experienced by people who possess those objects and qualities, which must first be produced. For instance, Mill argues that intellectual and moral pleasures are higher in quality than mere physical sensations of pleasure and can only be experienced by agents who possess the relevant intellectual and moral capacities, capacities that must be developed in part by the agents themselves (Riley, 2009, 2010).

Welfare as Preferences

Perhaps currently most influential, preference-oriented approaches conceive personal welfare in terms of personal preferences and social welfare in terms of social or moral preferences that are constructed in some way from the set of personal preferences. But there is an ambiguity in the key notion of 'preference-satisfaction': it may mean the fulfillment of preference by a suitable shift in the way the world is; or it may mean the satiation of preference by a suitable shift in the subject's conception of the way the world is. Proponents of preference approaches often insist on the latter 'satiation' interpretation because of their implicit subjectivism. Fulfillment without satiation (e.g., posthumous fulfillment of preferences) does not count. From this subjectivist perspective, hedonism may be viewed as a special case in which preference-satiation is equated with a mental state of pleasure including relief from pain. As already mentioned, however, classical hedonism is not a purely subjectivist doctrine. Some feasible pleasures are said to be embodied in material objects and human virtues, for instance, even if they are not at the moment being experienced. In any case, defenders of preference conceptions usually reject hedonism as implausible.

Two versions of the preference approach should be distinguished. One defines 'preferences' in terms of observable 'choice behavior' (see, e.g., Harsanyi, 1992; Binmore, 1994, 1998). A person's preference for x over y is 'revealed' by his choice of x when y is available, independently of his desires or other motivations for the choice. In contrast, the other version defines preferences as 'desires' rather than 'choices' (e.g., Hare, 1981; Griffin, 1986). A preference for x over y implies greater desire-satisfaction (though not necessarily greater pleasure) from x than from y. Nevertheless, the agent could – and perhaps should – still make a counterpreferential choice of y over x in this case. Of course, the notion of 'counterpreferential choice' makes no sense under the choice-oriented variant. But that approach is silent about the motivations people have for making the choices it views as comprising personal or social welfare. It needs to be supplemented by a theory of motivation, not only to explain why people do make those choices but also to justify why those choices ought to be seen as conducive to welfare. For its part, the 'desire approach' does not entirely lack a theory of motivation. But its theory may well be inadequate. It is arguable that people are not always motivated to choose the options that they expect will bring them the greatest satisfaction of their given desires, nor should they be. Perhaps they are, and ought to be, motivated to sacrifice or revise their greatest desires because they have moral commitments (Sen, 1977), for example, or because they wish to seize opportunities for mutual advantage that change from moment to moment (Sugden, 2004, 2010).

However preferences are interpreted, the main appeal of preference conceptions is often taken to reside in their implicit subjectivism: the welfare of any individual or society is judged from the subjective viewpoint of that particular individual or society. The contents of welfare judgments may vary significantly across different persons or social groups (*see* Diversity and Disagreement in Ethics: Philosophical Implications). Nevertheless, the appeal of any purely subjective interpretation of welfare is quite limited. People may be deluded, for example, or ill-informed, or resigned to their customary positions as slaves or 'untouchables' in highly stratified societies (*see* Irrationality: Philosophical Aspects). Their naked personal preferences may thus be poor indicators of personal welfare. Moreover, people may be unable to imagine themselves in others' shoes, or they may clash over interpersonal comparisons, or display undue bias against others' interests. As a result, they may fail to construct moral preferences that can serve as social welfare judgments.

Defenders of preference conceptions often respond to these difficulties by suitably laundering preferences. Conditions are specified that a person's choices or desires must satisfy before they can be accepted as conducive to his own welfare or that of his society. Thus, for example, Harsanyi (1992) suggests that a person's choices are conducive to his own welfare only if they are informed and conform to the expected utility axioms, whereas his choices are conducive to social welfare only if, in addition, they are impersonal. Impersonal choices must conform to the equiprobability model of moral choice and are used only to select an optimal code of moral rules. The person must forget his own position (defined broadly to include family history and genetic makeup) and imagine himself occupying the position of any person in society with equal probability. He must also extend sympathy to each person j by making the same choices j would make from the set of feasible codes while in j's shoes. Given the independent assumption that all persons share a fundamentally similar human nature (including attitudes toward risk used to measure the relative importance of different choices), which is revealed to anybody who fights against his biases by adopting the impersonal perspective of the equiprobability model, he can then infer interpersonal comparisons of cardinal utility which are identical to those inferred by anybody else who goes through this procedure. Finally, he must aggregate impartially over the cardinal comparable utilities he experiences at the respective persons' positions to construct moral preferences, which turn out to be (average) utilitarian in form. Once an optimal moral code is selected, individuals are free to compete over scarce resources by playing their permissible strategies under the rules.

Harsanyi's version of rule utilitarianism is vulnerable to numerous objections (Binmore, 1994, 1998; Riley, 2009). Moreover, even if such hypothetical preferences have some appeal as conceptions of welfare, the subjectivism which is usually thought to be the main strength of preference approaches is lost unless agents affirm the hypothetical preferences under the relevant conditions. To preserve an element of subjectivism, individuals and societies must willingly adopt those preferences before they can be said to be conducive to the welfare of those particular individuals or societies. If actual adoption of the preferences is a necessary condition of good, however, attention is redirected to psychological theories of evolution and education which explain how people develop the intellectual and moral capacities required to make the relevant choices or form the relevant desires (*see* Evolution, Natural and Social: Philosophical Aspects). It remains an open question whether a credible theory of this sort exists. But whether or not human capacities can be developed such that human beings invariably obtain the greatest desire-satisfaction from making moral choices, a credible psychological theory is needed. Some version of hedonism may yet prove plausible in this regard.

Welfare as Resources

In resource-oriented conceptions, personal welfare is defined in terms of an objective list of resources broadly defined, whereas social welfare consists implicitly of the effective production and fair distribution of the relevant resources (*see* Justice: Philosophical Aspects). Rawls (1999, 2005) can be read as offering such a conception, for example. He refers to 'primary goods' as 'things which every rational man is presumed to want' and 'things citizens need as free and equal persons,' and provides a (perhaps incomplete) list that includes 'basic rights and liberties,' 'freedom of movement and free choice of occupation against a background of diverse opportunities,' 'powers and prerogatives of offices and positions of responsibility in the political and economic institutions of the basic structure,' 'income and wealth,' and 'the social bases of self-respect.' Dworkin (2000) spells out another approach of this sort. (Kymlicka (2002) provides an excellent introduction to the wide-ranging critical debate surrounding such liberal theories of justice.)

There is little doubt that human welfare depends on the possession of such valuable things as those listed by Rawls or Dworkin. Data on the extent to which a person possesses these items may provide helpful indicators of different aspects of his good, even if the indicators cannot be combined into a single index of personal welfare. Similarly, data on the social distributions of these things may provide indicators of different dimensions of social welfare, with the same caveat.

Nevertheless, in addition to the specific objections which may be directed against a particular theory such as Rawls's or Dworkin's, resource conceptions face at least two general difficulties. First, it seems that the relevant resources are conducive to welfare only because they are objects of suitably laundered preferences. As Rawls suggests, for example, primary goods are things which every person would prefer to have if he were rational and reasonable. Furthermore, since a person's holdings of one resource (say, political responsibilities) can interfere with his holdings of another (say, wealth), it seems that his preferences must settle which of many different mixes of resources is best for his welfare. Similarly, it seems that moral preferences are needed to settle which among many competing social distributions of resources are permissible if not essential to promote social welfare. If this is right, resources may well be essential ingredients of welfare but they properly figure as objects of preferences.

The second difficulty is that resource conceptions do not take account of interpersonal variation in human capacities to convert resources into the achievement of human functionings (Sen, 1990). This problem leads to another way of conceiving welfare.

Welfare as Capabilities

Sen (1985a,b, 1990, 2004, 2009) argues that human well-being should be conceived in terms of 'capabilities' – or 'positive freedoms' (*see* Freedom: Political) – to achieve valuable human 'functionings' given by some objective list (see also Sugden, 2008; Basu and Lopez-Calva, 2010). He points out that different people may have unequal capabilities to convert resources into achievements. Physically handicapped people may need more income than the able-bodied need to achieve a given level of mobility, for example. People who are genetically vulnerable to particular diseases may need more medicines than the less vulnerable need to achieve a given standard of health. Women may need more food than men need to achieve a given standard of nutrition. Racial minorities may need more educational and job opportunities than white males need to achieve a given level of career success if racist attitudes are prevalent. The elderly may need more wealth than the young need to achieve a given standard of living. These are essentially empirical questions.

Such examples suggest that capability conceptions can remedy a serious deficiency in resource approaches to welfare. But, as with resources, it seems arguable that certain capabilities are properly viewed as essential components of welfare because they are objects of suitably laundered preferences. Some capabilities are in effect things that every rational or moral person is presumed to want or choose. To the extent that anybody lacks these benchmark freedoms, reasonable people may agree that some form of special compensation ought to be provided so that the person can function 'normally,' for example, income subsidies, extraordinary medical assistance, affirmative action in hiring decisions, and so on. Furthermore, beyond the benchmark capabilities which everyone is presumed to need, it seems that a person's preferences must determine which balance of extra capabilities is proper for his welfare since capabilities to achieve some functionings can presumably interfere with capabilities to achieve others. Again, since one person's capabilities might interfere with another's, ethical preferences are needed to settle which of many competing social distributions of capabilities (including benchmark capabilities) is permissible if not essential to promote social welfare.

Combining Insights

Perhaps some version of the preference conception of welfare may have appeal as a way to combine insights from the various approaches to welfare. The upshot seems to be that, to serve as a personal welfare judgment, a person's preferences must be suitably laundered not only to satisfy certain formal conditions of rationality but also certain substantive conditions. In particular, the preferences must demand a personal share of certain all-purpose resources which every rational person is presumed to want, making due allowance for interpersonal variation in capabilities. Moreover, a credible psychology is required to explain how individuals come to form the relevant preferences.

It might be argued, for instance, that a person's welfare is happiness in the sense of pleasure, that a desire for any object or thing is proportional to the pleasure expected – perhaps mistakenly – from it, that mistaken beliefs ought to be corrected, that strongest present desires determine choices, that repeated choices may result in habitual attitudes or dispositions in which the original motivating pleasures are forgotten, and that habitual choice behavior reveals preference rankings that can be represented by utility functions. Other hypotheses may be more plausible, of course. But some such integrated preference-oriented approach appears essential.

To serve as a social welfare judgment, preferences must satisfy, in addition, certain moral conditions, including formal conditions of impartiality or impersonality as well as substantive conditions of fairness in the distribution of all-purpose resources making due allowance for capabilities. A social decision procedure that maps any given set of personal welfare judgments into a social welfare judgment thus understood must be specified. Again, a credible psychology is needed to explain how individuals develop the intellectual and moral abilities required to make and endorse the relevant moral preferences.

If a laundered preference approach has such potentially broad appeal, *welfarist* moral philosophies might adequately capture the phenomenon of human welfare, as Sumner (1996) maintains. To consider this question, suppose initially that personal welfare rankings can invariably be represented by technical utility functions, and that this utility information is all that matters for the construction of moral preferences which can also be represented by utility functions.

Standard Welfarist Philosophies

Standard welfarist philosophies are distinguished by their exclusive reliance on welfare rankings, which I am construing as laundered preferences, and the utility functions that represent them. Perhaps the most well known examples of such philosophies are the standard versions of utilitarianism. But there are many different forms of welfarist philosophies. They can be clarified by means of the concept of a *social welfare functional* (SWFL) (Sen, 1986: pp. 1111–1128). For a given set of options, any SWFL maps a given set of personal utility functions (one for each person in society) into a social or moral preference which can itself be represented by a utility function. Since each person's utility function is an element of some family of informationally identical utility functions as determined by the given assumptions of measurability and comparability, however, the SWFL is required to satisfy an invariance requirement: it must generate the same preferences if any given set of personal utility functions is subjected to transformations permitted by the measurability and comparability assumptions.

Welfarism is a neutrality condition imposed on the form of an SWFL. It requires that if each person's utility values with respect

to one pair of options x and y are equal to his utility values with respect to another pair w and z – subject to transformations permitted by the given measurability and comparability assumptions, then the SWFL must generate the same social or moral preference over the one pair as over the other. The only information that matters for a welfarist SWFL is utility information. Nonutility information has no influence.

Arrow's (1963) well known 'impossibility theorem' shows, roughly, that any welfarist SWFL must be dictatorial if personal utility functions are ordinal and noncomparable. But a dictator only counts his own personal preferences: he sympathizes with nobody else to determine social preferences. (For variations and extensions of Arrow's theorem, including its extension to the case of cardinal noncomparable utilities, see Sen, 1986: pp. 1073–1076, 1114–1115.) A welfarist SWFL that is impersonal in so far as its operation does not depend on any person's identity is possible, however, if interpersonal utility comparisons are possible. As Harsanyi's equiprobability model illustrates, an impersonal observer can be assumed to make the interpersonal comparisons by extending sympathy to each person while in that person's position. The observer is an ideal moral agent who supposedly makes comparisons which all reasonable people with capacities of imaginative sympathy would agree to make. This idea that there is one right way to make interpersonal comparisons is implicit in the design of many other welfarist SWFL's and seems essential to generate incontestable moral preferences. The idea is highly implausible, however, so that there are serious doubts that an adequate philosophy of human welfare can be put into a welfarist form.

Nonstandard Welfarism

Nevertheless, an intriguing possibility is given by the liberal utilitarian philosophy which I have attributed to J.S. Mill (Riley, 1988, 2010, 2012, 2014). As I now understand it, the Millian philosophy is a nonstandard form of welfarism in which a welfarist SWFL is restricted in its operation to a higher kind of preferences associated with the moral sentiment of justice, with justice conceived in terms of a moral and legal code of equal rights and duties for all, whereas individuals are free to pursue their other kinds of preferences (which may be unstable or incoherent) in accordance with their recognized rights and duties because society has no need to map these other kinds of preferences into a social or moral preference ranking. To facilitate this, the neutrality condition imposed on the SWFL must be suitably restricted in scope such that it refers only to the higher kind of preferences and does not apply across the different kinds. In effect, the Millian welfarist SWFL, which generates a moral kind of social preference from any given set of a moral kind of personal preferences, all of which can be represented by utility functions, makes possible an 'enlarged' utilitarian 'art of life' that is compatible with, though it extends beyond, the welfarist morality. The enlarged philosophy prescribes freedom for individuals and groups in domains that are beyond the moral realm of the SWFL, including a purely personal domain as well as a competitive market domain. There is no presumption that individuals will form preferences that can be represented by utility functions in these nonmoral domains.

Although I cannot go into the details here, three further points need to be made about this unusual form of welfarism. First, the different kinds of preferences are ultimately motivated by different kinds of pleasures, some of which are intrinsically more valuable than others are as pleasure, and the different kinds have different sources. In particular, the pleasant feeling of justice is held to be of a higher quality than any competing kinds of pleasure, irrespective of quantity (Riley, 2010, 2012). Codes of equal rights and duties are the only source of this higher kind of pleasure: it is a complex feeling of security which an individual can only get by living with peers under a binding code which he or she has a voice in creating.

Second, competent human beings discover the ranking of the different kinds of pleasant feelings in terms of their quality by experiencing them, a ranking which is confirmed not created by the preferences of the vast majority if not all experienced people. Again, the higher pleasures doctrine is not purely subjective: the higher kinds of pleasures are latent in human nature, awaiting discovery by those who develop their intellectual and imaginative capacities. (Since humans are fallible, some disagreement over the qualitative ranking remains possible.) According to Mill, the different kinds can be distinguished without relying on values other than pleasure, just as colors can be distinguished without relying on anything other than color. (Many philosophers, following Sidgwick and Moore, reject this. Yet Mill may be correct that desiring something and thinking it desirable are just two modes of naming the same psychological fact, i.e., the fact that the person associates some kind of pleasure including relief from suffering with the thing.) In any case, the qualitative ranking of the kinds of pleasures, even if unanimously shared by those who are 'competently acquainted' with the different kinds, is a lexical preference that cannot be represented by a technical utility function. Any higher kind of pleasure is discontinuous in value with any lower kind: any amount of the latter which humans can experience can never be equal in value to even a bit of the former as pleasure.

Third, with respect to the operation of the welfarist SWFL in its limited moral domain, it seems necessary to concede that it is too costly if not impossible to make interpersonal utility comparisons which every competent person accepts. (Interpersonal utility comparisons are not otherwise needed since individuals and groups enjoy liberty outside the moral domain.) Even if such comparisons are abandoned and we are left with purely ordinalist utility information, however, welfarist SWFLs can employ artificial devices to generate a moral preference for society from any given set of the moral kind of personal preferences. Thus, for instance, a Borda SWFL does not rely on interpersonal comparisons and yet generates a social welfare judgment that can be represented by a utility function. It works by employing a rather artificial yet impersonal scheme of points (i.e., ballots) to supplement the utility information contained in any given set of personal preference orderings. (This Borda procedure avoids Arrow's impossibility result by effectively modifying the Arrovian neutrality condition.)

Beyond Welfarism

Although such a nonstandard welfarist philosophy is of considerable interest, the possibility remains that a nonwelfarist moral philosophy – one that relies to some extent on nonutility information, that is, information which is not contained in preference rankings or the utility functions representing them, to produce moral choices for society – may have even more appeal. Such a philosophy might be based on an accurate description of human behavior, for example, even though the goal of maximizing welfare is dropped. Myriad forms of nonwelfarist philosophies are conceivable. Such a philosophy may take the form of an SWFL that does not satisfy the relevant neutrality condition. The nonwelfarist SWFL might make use of nonutility information about the feasible options to generate different social preferences over two pairs of options, even though the utility information relating to the two pairs is identical. One pair might belong to an individual's rightful 'protected sphere' whereas the other does not, for example, or the nature of the options in one pair might involve the oppression of some minority whereas the options in the other pair involve no such oppression. The social preference ranking generated by the SWFL can still be represented by a utility function but the social preferences over the two relevant pairs of options will not be the same even though the personal utility information is identical with respect to those pairs.

Nonwelfarist philosophies may instead eschew the form of an SWFL. Binmore's (1994, 1998) evolutionary cooperative game structure does not attempt to generate social preference orderings of feasible options, for instance, and assigns a special status to the prevailing Nash bargaining equilibrium instead of satisfying a neutrality condition (see also Sugden, 2001; Riley, 2006). To take another example, Sugden (2004a,b, 2011) proposes a coordination game framework in which social outcomes are not deduced from given sets of personal preference rankings but instead reflect mutually advantageous conventions that are induced by individuals on the basis of shared perceptions of salience or 'focal points.' A nonwelfarist philosophy might also take a value pluralistic form (*see* Value Pluralism), in which welfare is only one of plural irreducible values in ethical evaluations. Sen (1985a,b, 2004, 2009) proposes a pluralistic structure in which the value of 'well-being' cannot be reduced to that of 'agency,' for instance. By implication, indeterminacy may arise in all-things-considered ethical preferences if well-being comes into conflict with agency.

Welfare Policy Comparisons

Gosta Esping-Andersen, Universitat Pompeu Fabra, Barcelona, Spain

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The author reviews the three dominant questions within the comparative welfare state literature: one, how does one explain policy variations across countries and time? In particular, what has been the relative importance of political power, industrial modernization, and other historical factors? Two, are welfare states sustainable in an era of heightened globalization? Three, how do such variations influence welfare outcomes, in particular related to income distributions, poverty, family life, and gender relations?

Introduction

Welfare policy comparisons have been a prominent feature of macrolevel social science research since the 1970s. Dominated by political scientists and sociologists, the focus is primarily on the advanced industrial democracies. The literature is guided by two overarching kinds of questions: one, how does one explain the rise of welfare states, their diversity, and, more recently, their adaptation to the new global economic order? Two, how do variations in policy design affect welfare distributions? This article will treat the two questions separately.

It has been difficult to arrive at clear-cut answers to either question because of statistical overdetermination; the number of rival explanations often exceeds the number of cases that can be studied. There are, moreover, conceptual difficulties because scholars do not always compare and explain the same phenomenon. Some compare specific social policies (say pensions), others welfare states, and still others welfare regimes, and the difference is rarely made clear. The presence of a set of social policies does not automatically imply a welfare state, which, following Marshall (1950), implies social entitlements as a matter of citizenship, comprehensive risk coverage, commitments to full employment, and active reduction of inequalities. The welfare state is also an ideological construct, a means to inculcate broad solidarities and national integration. Rather than speaking of more-or-less welfare statism, the literature has increasingly favored typologies of kinds of welfare states. Many scholars use the concept of welfare regimes to denote the broader complex, or mix, of social welfare provision between state, market, and families (for a discussion, see Esping-Andersen, 1999).

Conceptualizing Welfare Policy Models

Early quantitative comparisons, such as Wilensky (1975), compared welfare policy differences through national social spending levels. This was challenged on validity grounds (spending may not reflect welfare effort, and it tells one little about what kind of welfare is being produced and for whom). As a result, research in the past two decades has been greatly concerned with the precise meaning and content of social policies and the welfare state. Most conceptualizations begin with Marshall's (op. cit) emphasis on the rights of social citizenship, and programs are then compared in terms of the strength of entitlements, to what extent they lessen market dependency ('decommodification'), and to what degree rights are universal or differentiated (Flora and Alber, 1981; Korpi, 1983; Esping-Andersen, 1990). More recently has emerged an explicit gender perspective aiming to identify how welfare policies influence gender relations and, more broadly, the revolution of women's roles (O'Connor et al., 1999; Gornick and Meyers, 2003; Esping-Andersen, 2009).

The greater conceptual attention to policy content and objectives led to a keener appreciation of the qualitative differences between national welfare systems. Drawing upon Titmuss (1974), there emerged a voluminous literature on welfare state typologies, initially focused on welfare state models. As research expanded to the interplay among state, market, and family provision, emerged classifications of welfare regimes, such as the liberal, conservative, and social democratic trichotomy in Esping-Andersen (1990) and further refinements, such as Castles' (1993) notion of a unique Antipodean 'wage earners' model,' the identification of a highly familialistic and patronage-based Mediterranean model (Ferrera, 1996; Esping-Andersen, 1999). Some feminist writings have proposed typologies based on the strength of the conventional male breadwinner assumption (Lewis, 1993). With the exception of the latter, most typologies classify nations rather similarly: a Nordic group, distinguished by its universalism, comprehensive coverage, generosity, and a strong commitment to gender equalization; an Anglo - Saxon group, characteristic for its residual public provision, its targeting of benefits, and its encouragement of private welfare; a Continental European group, which stands out for its corporativistic status-segmented social insurance; and, more controversially, a Mediterranean (and, possibly, East Asian) group primarily distinguished by its strong accent on familial welfare provision. As Castles (1993) points out, these typologies resemble 'families of nations,' nation clusters with a deep common historical tradition. Recent years have seen a renewed debate on whether the 'Three Worlds' typology still remains valid in light of decades of policy change and reform. On balance, the answer is largely confirmative (Arts and Gelissen, 2010). This is consistent with Pierson's (1996) influential theory of institutional path dependency – the resiliency of institutions once they are firmly implanted.

Explaining Policy Divergence

The great vitality of comparative welfare state research comes from its address to central theoretical issues in the social sciences. Existing reviews of the literature usually distinguish two broad explanatory thrusts: the convergence thesis, which derives from theories of industrialism and modernization, and the 'politics matter' thesis, which derives from theories of conflict and power mobilization (Esping-Andersen and Van Kersbergen, 1992). In addition, some theorists emphasize the process of nation building and democratization (Flora and Alber, 1981), nations' position in, and response to, the world economy (Cameron, 1978; Katzenstein, 1985), and also the policy-making role that state bureaucracies exert (Skocpol, 1985).

The Modernization Thesis

The earliest systematic welfare state comparisons were chiefly inspired by the theory that industrialization (accompanied by urbanization, the rise of efficient bureaucracy, and demographic aging) erodes traditional social protection mechanisms, such as the family, and makes public responsibilities necessary. As nations industrialize, they will also converge because social risks become more similar, and because the functional necessity of public social security becomes pressing. Main exponents of this thesis include Rimlinger's (1971) as yet unrivaled historiography of the roots of welfare policy in Europe, America, and Russia, and Wilensky's (1975) quantitative demonstration that rich countries gradually converge in terms of the share of gross domestic product spent on welfare. Wilensky provided no direct measure of political variables, and his conclusions were therefore challenged by adherents of the 'politics matter' position.

The 'Politics Matter' Thesis

The resurgence of conflict theory in the 1970s provoked two antitheses to the modernization paradigm. One was Marxian and quite functionalist, arguing that the modern welfare state was not an egalitarian response to new needs, but rather a mechanism, however contradictory, of sustaining the legitimacy of capitalist economies (Offe, 1972). This perspective has produced no real systematic empirical comparison.

The second antithesis argues explicitly that 'politics do matter' in the sense that the nature, scope, and objectives of a welfare state depend primarily on the balance of political power between 'left' and 'right.' Since it is well established that the roots of welfare policy are largely conservative, as in the case of Bismarck, this position is mainly concerned with welfare state variations in mature industrial democracies. The premise is that the collective resources of wage earners can, through parliamentary democratic means, be mobilized so as to establish a kind of welfare state that effectively modifies the distributional outcomes of markets and the decisional power of capital (Korpi, 1983). This thesis lies close to classical social democratic theory and its postulate that a parliamentarian transition from capitalism to democratic socialism is possible (Stephens, 1979). It is accordingly often labeled the 'social democratic' model of the welfare state. Since Sweden epitomizes social democratic power and achievement, the thesis has been criticized for its inherent swedocentrism.

The power mobilization hypothesis has given rise to not only a very large but also conceptually and methodologically heterogenous literature, which, cumulatively, makes a strong case in favor of the underlying thesis. Whether studying individual social programs, such as pensions, sickness benefits, or labor market policies (Myles, 1984; Korpi, 1989, 1991), or more broadly 'welfare states' (Stephens, 1979; Korpi, 1983; Esping-Andersen, 1990; Hicks, 2000), the impact of the political strength of the left is quite robust.

Still, the 'left power' explanation is questioned by several authors who work within the 'politics matter' tradition. Some argue against a simple, linear left-power effect, arguing that real politics are premised on enduring party coalitions. Postwar Christian Democracy, for example, has been seen as a functional equivalent to labor movements, producing similarly generous welfare states. Esping-Andersen (1990, 1999) and, especially, Van Kersbergen (1995) demonstrate, however, that Christian Democracy produces welfare states that may be generous, and that are also strongly corporativistic in design, very 'familialistic,' and transfer biased. They also tend to be biased in favor of upholding the traditional male breadwinner family model (Esping-Andersen, 2009). In a unique synthesis of the modernization and politics-matter theses, Pampel and Williamson (1989) suggest that all governments, left or right, will favor welfare expansion because population aging implies also median-voter aging.

The Impact of Globalization

The literature is quite divided on how economic globalization influences welfare state development. Following Cameron (1978) and Katzenstein (1985), some adhere to the 'compensation' hypothesis, arguing that strong social guarantees are *sine qua non* in small, open economies that face stiff global competition. Others, however, argue that global competitiveness is harmed by generous social provisions and heavy tax burdens, thus putting downward pressures on welfare spending. For an overview, see Glatzer and Rueschemeyer (2005). There is, so far, no clear consensus on which interpretation is most credible because the precise causal connection has been difficult to identify empirically. Recent scholarship does highlight major and far-reaching reforms within advanced welfare states that seem to challenge Pierson's (1996) path-dependency thesis (see especially Palier, 2010). How these are causally related to globalization remains unclear.

Nation Building and Democratization

The puzzle that any 'politics matter' explanation faces is that the first social reformist steps were usually taken by conservative, often antidemocratic forces, aimed at containing working class mobilization (Rimlinger, 1971; Flora and Alber, 1981). Social policy per se cannot therefore be a sufficient indicator of left-political achievements. The issue is really one of

historical sequence. Most would agree that the historical roots of social policy are closely connected to late-nineteenth century nation building, a means to sustain the established order in the face of emerging social, linguistic, ethnic, or religious cleavages. The 'politics matter' paradigm, in contrast, is concerned with the epoch of actual (and programmatically explicit) welfare state construction in the postwar era of full democracy.

The State-Centered Thesis

Modernization theory stresses the functional necessity of efficient bureaucracy for welfare state development because, without it, effective taxation and administration of complex distributional programs is simply impossible. Bureaucracy, once erected, may also come to play an active role in decision making and thus determine policy evolution. Heclo (1974) maintained that Swedish and British welfare policy, although originally rather similar, eventually parted ways because of inherently different bureaucratic policy-making traditions. The independent powers of public officials in framing key policy decisions have received particularly strong emphasis by Skocpol (1985). This so-called state-centered thesis has proved difficult to test empirically against rival arguments. As a result, empirical applications are limited to select case studies that are difficult to generalize and a handful more systematic, quantitative studies (Korpi, 1989).

The Consequences of Welfare States

The literature on the consequences of welfare state differences is, possibly, as huge as the former but the protagonists tend to be different. For one, there is a long-standing tradition in Economics to study the microeconomic effects of social policies on labor supply as well as their macroeconomic effects on inflation, savings, unemployment, or economic growth. This literature, which, in any case, is rarely comparative, will not be reviewed here (for an overview, see Barr, 1993).

Closer to our concerns are studies that examine the impact of welfare state design on distributional outcomes. Most scholars agree that the focus should be on life chance dynamics, but this has been limited by data scarcity. The literature is therefore dominated by cross-sectional analyses of income inequalities, poverty, and, in recent years, also on gender equality.

Poverty and Income Distribution

The conventional assumption has been that equality is positively and linearly related to welfare state generosity. This was implicit in Wilensky (1975), and some early attempts at empirical verification produced positive and significant correlations (Hewitt, 1977). Until the mid-1980s, however, robust comparisons were hampered by problems of cross-national data comparability. Only with the advent of the Luxembourg Income Study and, later, European Union data collection, did genuinely comparable income data become available.

Most studies of the redistributive effects of welfare states (or single social programs) compare pre- and posttransfer tax distributions (representative recent examples include Smeeding (2005) and OECD (2011)). An extensive review of the literature is found in Esping-Andersen and Myles (2009). For a focus on poverty-reduction effects, see Kenworthy (1999) and Nolan and Marx (2009). A few studies involve more explicitly the impact of types of welfare states or social policies on distributional outcomes (Palme, 2006).

Quantitative comparisons come to a surprisingly consensual view: the larger the welfare state, the greater the degree of equality in net disposable income, and the lower the rates of poverty. A less obvious finding is that welfare states targeted to the truly needy do not result in more poverty reduction than does the universalistic approach to social protection (Korpi and Palme, 1998). Reflecting the paucity of comparable panel data, studies on poverty and inequality dynamics are, so far, few. Preliminary evidence does, however, suggest that comprehensive, generous welfare states are substantially more able to guarantee against long-term entrapment in poverty or welfare dependency (OECD, 2011). This appears to hold also for the recent decades of rising economic pressures (Kvist et al., 2012). Most studies conclude that targeted, means-tested policies create strong poverty traps.

The finding that comprehensive, universalistic welfare states are more redistributive than those favoring heavy targeting has provoked debate about the precise mechanisms involved. Some argue that income tests create stigma and lowers the take-up rate. With their notion of the 'paradox of redistribution,' Korpi and Palme (1998) argue that the basic reason is that comprehensive and universalistic policies crowd out inequality-producing private welfare plans.

Almost all research is limited to the effects of government income transfers and taxation and very little is known about the redistributive effects of services. A rare exception is Marical et al. (2006) who show that welfare state services have a substantial redistributive effect, particularly in service-intensive welfare states like the Nordic (see also Esping-Andersen and Myles, 2009).

Gender Inequality

One has witnessed a rapidly growing literature on the impact of welfare states on gender inequalities, in particular via family policies, such as caring services and leave schemes. Specific policy variations are linked to either welfare state typologies (as in the case of Gornick and Meyers, 2003; Stier et al., 2001), or to male breadwinner typologies (Lewis, 1993), and welfare systems are often ranked in terms of their degree of 'women friendliness' (for an overview, see O'Connor, 1996). A number of rather clear-cut empirical conclusions have emerged. One, day care provision is a powerful precondition for women's economic independence, for their capacity to harmonize careers and family, and also for safeguarding against poverty in single-parent families (Gornick and Meyers, 2003). A second finding is that welfare systems that grant women independent entitlements enhance both individual autonomy and gender equality (O'Connor et al., 1999).

A parallel line of research focuses on demographic outcomes, fertility in particular. The core argument is that gender egalitarian policies are becoming a precondition for decisions regarding motherhood (McDonald, 2006; Duvander

and Lappegaard, 2010). While family allowances seem to have no effect, child care provision promotes fertility significantly (Gauthier, 2007; D'Addio and Ercole, 2005; Neyer and Andersson, 2008) and this is also the case for paternity leave schemes, at least in Sweden (Olah, 2003). The impact of maternity leave seems to have less to do with their duration than with inbuilt job-retention guarantees (Neyer and Andersson, 2008). More generally, the connection between welfare state commitments and gender equalization remains causally ambiguous. As argued by Esping-Andersen (2009), one faces a problem of endogeneity to the extent that such welfare reforms mainly emerge when the revolution of women's roles is quite advanced.

Welfare Reform

Torben M Andersen, Aarhus University, Aarhus V, Denmark

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The fundamental question in welfare system design and thus reforms is how to balance concerns for efficiency with equity. The key issue is how to strengthen employment incentives while maintaining social insurance and ensuring an acceptable distributional profile. The main drivers underlying recent reforms are unemployment problems, changing demographic structures, and strained public finances. The trend and issues in recent welfare reforms are reviewed with a focus on how to make high employment consistent with distributional objectives.

Introduction

Welfare reforms are high on the agenda in many OECD countries at the same time as several emerging economies are contemplating how to develop and extend welfare systems.

The use and understanding of the term "welfare reform" is not unequivocal but depends on the welfare regime (Esping-Andersen, 1990). Thus in political discourses in the Nordic countries the term "welfare" is used synonymously with tax-financed welfare state arrangements including both the social safety net and public service provisions. In Anglo-Saxon countries the term "welfare" refers more narrowly to social benefits targeting the poor. In the following, the broad interpretation is used. Likewise a distinction is sometimes made between social welfare benefits and social insurance, where the former is means-tested and the latter event conditioned, cf e.g., Feldstein (2007). This distinction is not clear-cut since the need for benefits is also event conditioned and all welfare arrangements in general include an implicit or social insurance element. Social–implicit insurance is here used in the broad sense of insurance arrangements embedded in tax financed welfare state arrangements.

The basic purpose of the welfare state is to ensure that individuals are protected against social events which can happen through life and which preclude self-support or in other ways affect life conditions (e.g., health) significantly. The causes of such events can be idiosyncratic or aggregate arising from developments in society (business cycles, structural changes etc.). The financial crisis has brought the issue of the importance of collective risk sharing arrangements to the fore in policy discussions.

A main driver of welfare reforms in recent years has been the problem of ensuring the financial viability of welfare systems. Public finances are in most countries under stress due to high debt levels and large budget deficits, not least due to changing demographic structures. The financial sustainability of tax-financed welfare systems is thus under pressure, although it should be noted that the extent of these pressures is not correlated with the size and scope of welfare systems, but rather reflects differences in political abilities and willingness to undertake appropriate reforms in due time.

Lack of financial viability is an obvious reason why reforms are needed, but structural changes in society, including technological developments and globalization in its broad sense, may also change both the benefits and costs of social arrangements. It is not obvious that past designs of welfare systems provide the right answers to current and future challenges. On the one hand the need for welfare arrangements may increase due to a higher pace for structural changes as well as widening inequalities in labor markets, while on the other hand the scope for and consequences of tax financing may be changing.

The use of the term "reform" is often inflated in political discussions where any policy change, small or large, is denoted a reform with the implicit understanding that it is making a change for the better. Analytically it is useful to make a distinction between systemic, parametric, and regulatory/administrative reforms. A systemic reform involves fundamental changes in the principles underlying policies in a specific area, a parametric reform changes certain parameters (e.g., the replacement rate, eligibility condition) within the confines of the existing system, and a regulatory/administrative reform addresses legal, organizational, and administrative issues. There are very few systemic reforms, especially when it comes to the overall structure of welfare state arrangements. Welfare regimes are very persistent. A recurrent theme is whether there is a race-to-the-bottom in the sense that a minimal welfare state will prevail. Assessed in terms of the overall size of the public sector for OECD countries, there is no sign of such an effect, and the relative size of the public sector across countries has been very persistent for decades. There is a continuous stream of small and large parametric and regulatory–administrative reforms, and it is not possible to provide a reliable and simple quantification of these reforms. Especially tax, labor market, and pension reforms have been frequent in recent years. A distinction is sometimes made between macroeconomic policy and structural reforms, where the former addresses aggregate issues via primarily fiscal and monetary policy, while the latter deals with the specific design of tax, social, and labor market policies. This distinction has become more blurred since structural issues, in particular pertaining to the labor market, are core issues in modern macroeconomics.

Welfare reforms capture potentially quite wide policy areas including social, labor, pension, health, care, housing, and migration. In the following, welfare reforms are discussed in relation to the design of the social safety net, and the question of how to reconcile equity and efficiency, that is, social protection and insurance with high employment, is addressed.

Welfare Regimes

Welfare reforms are often controversial and ignite vivid political debates. Reform agendas are frequently labeled as retrenchments of the welfare state or taken to imply that neoliberal views are gaining ground. In these discussions, it is important to distinguish between reforms induced by changes in political objectives for unchanged fundamentals and reforms driven by changes in fundamentals for given policy objectives. If current welfare arrangements are not financially viable, a quest for reforms may derive from a desire to protect basic social objectives. Not all reforms are retrenchments in the sense that social objectives have changed. In addition economic problems and crises may shift political barriers which have postponed reforms and thus become a vehicle for reforms (crisis-driven reforms).

New insights and knowledge may act as a catalyst for policy changes. If evidence shows that incentives have different effects than (perceived) in the past, it is to be expected that this will lead to policy changes for unchanged policy objectives. An important advance in policy design in recent years is the more systematic use of effect studies. This is reflected in a stark contrast between the current approach to reforms compared with the 1970s and 1980s. In that period many countries attempted to solve unemployment problems by reducing labor supply (early retirement, disability, sickness pensions). In recent years reform initiatives have been taking a more direct approach focusing on strengthening incentives for job search and creation. This shift is driven by a concern that passive policies did not address the underlying causes of unemployment problems and that they may create other social problems (stigmatization, benefit dependency etc.). Moreover such passive policies strain public finances. Therefore the recent focus is on reforms that seek to boost labor supply and hence employment both as an objective in its own right but also as a means to improve public finances.

A key challenge for recent welfare reforms has been how to boost employment without compromising distributional objectives. At the risk of oversimplifying it is possible to make a distinction between two different approaches to tackle this policy dilemma: the targeted approach versus the universal approach. The targeted approach aims at ensuring that help is directed to the deserving based on a 'work first' principle; that is, work should pay and low pay may then be supplemented (e.g., via an earned income tax credit) to ensure an acceptable living standard for those willing to work. The universal approach provides benefits as an individual right to ensure a living standard consistent with distributional preferences, and then attaches various conditions to ensure that recipients are directed toward regular work (employment subsidies, active labor market policies, education etc.). The former approach may be associated with Anglo-Saxon countries and the latter with Northern-European and Scandinavian countries. Both approaches have their pros and cons. The 'work first' model tends to penalize those who have difficulties in working, while the European model will reach those groups but tend to reward those who are less willing to work (enjoy leisure).

These properties seem to suggest a straightforward trade-off between efficiency and equity, leaving different policy positions captured by these two different approaches. However, this is contested by comparisons of the two models in terms of employment and distribution. It is well known that employment rates in Scandinavian countries with strong elements of the universal model are as high as in the US. The universal model is often portrayed as paying people for not working (Rogerson, 2007) or as making work unnecessary (Esping-Andersen, 1990). This effectively amounts to assuming that there is a basic income or demo grant, implying an unconditional minimum income for everybody. Basic facts on employment performance contradict this interpretation. This suggests that there are important facts concerning the design of welfare systems which are crucial for labor market performance, and thus important in discussions on welfare reforms.

Incentives and Insurance

Standard economic theory teaches us that there is a fundamental choice to be made between efficiency and equity. The more equity is pursued via social transfers and taxes, the more economic incentives are distorted (Mirless, 1971).

The distortions imply that employment is too low from a social point of view. This is the cost of ensuring a more equitable output. Sometimes policy debates take the view that distortions are to be avoided, but that would imply that equity is sacrificed. Standard economic theory does not imply that distortions should be avoided, but that they should be balanced to the gains from intervention.

The standard trade-off perception, however, does not take market failures into account. If markets are imperfect and incomplete, social insurance or welfare arrangements may be justified on efficiency grounds. This has wide implications, which is captured by the basic insight that redistribution and insurance cannot be separated (see e.g., Varian, 1980). Any scheme, which ex post based on characteristics like work, health, income, etc. provides entitlements or financial contributions, will *ex ante* serve an insurance function to the extent that there is some risk associated with which states of nature will prevail. If agents are risk averse, and private markets fail to provide sufficient insurance, it follows that there is an efficiency argument for the provision of social insurance. Related, the provision of insurance may not only have a direct welfare effect but may be conducive to flexibility and adjustment, e.g., via better job-matches (Diamond, 1981). Hence, up to some level extension of welfare arrangements may thus improve both efficiency and equity. In the second best context the issue of efficiency and equity effects of various policies is much more complicated.

Any insurance arrangement – private or social – suffers from the common pool or moral hazard problem. The provision of insurance distorts incentives since agents do not bear the full benefits/costs of their actions. In principle there is no difference in this respect between a private insurance scheme with an explicit payment of a premium and an implicit tax financed insurance scheme. The moral hazard problem arises due to a common pool problem and is in this sense generic to any type of insurance (although usually termed a distortion when tax financed). However, this does not imply that moral hazard problems are of no importance, the implication is that the incentive problems arising under social insurance should be evaluated taking into account what the realistic alternatives are.

In this respect is it interesting to observe a contrast – or perhaps even an inconsistency – between the micro and macroperspective on welfare arrangements and their financing. To see this, consider first the problem from an individual perspective in a stylized setting. The net gain from finding a job is $(1-t)w-b$, where w is wage income, t the tax rate and b the benefit level (nontaxable) assumed to be available to all not having a job. This net gain can be written $w-wm$, where the marginal effective tax rate ($METR$) is given as $m=t+b/w$; i.e., the sum of the tax rate t and the replacement rate (b/w). The higher m, the lower the net return to work, and this distorts the incentive structure. Next, consider the public budget focusing only on the revenue from labor income taxation and expenditures on benefits. We have that the budget balance can be written $B=twL-(N-L)b$, where L is employment and N the population (all are assumed eligible for benefits if out of job). The budget can be written $B=wmL+bN$, i.e., the effect on the budget of a change in employment L is wm; i.e., the higher the m, the more sensitive the budget is to changes in employment. In the microcontext a high m is considered a problem since it lowers the net return to work, while in a macrocontext it is praised since it captures the automatic budget response which is generally perceived to be stabilizing (hence termed automatic stabilizers). This points to the tension that reforms strengthening the individual incentive structure may reduce overall stabilization power and thus lead to more risk and volatility (see e.g., Knieser and Ziliak, 2002).

However, the size of automatic stabilizers is not a direct result of macrodesign but rather a byproduct of policy choices in relation to tax, social, and labor market policies. The automatic stabilizers are the net outcome of these choices, and therefore they vary substantially across countries. It is well known that there is a tight correlation between the strength of the automatic stabilizers and the extent of welfare arrangements measured by the size of the public sector. It is implied that it is not possible to make a sharp distinction between macroeconomic policies and structural policies.

Employment and Distribution

The issue of how to balance concerns for efficiency (employment) with distributional objectives can heuristically be thought of in terms of the following three elements.

1. Wage determination: Distributional ambitions determine benefit levels in the broad sense of social assistance, unemployment benefits (duration, eligibility, replacement rate) and minimum wages (either explicitly or indirectly via the level of social and unemployment benefits). It is a robust theoretical result that various wage models (competitive, bargaining, efficiency wages, etc.) all imply that wages depend positively on benefit levels. This may be phrased in the sense that benefit levels determine a floor or base for the entire wage distribution. Ambitious distributional objectives may in this sense preclude 'working poor.'

   The standard approach in the literature is to think of wage compression as something which impairs the market mechanism and thus is associated with inefficiencies. This need not be the case. Decentralized wage setting does not necessarily get close to the textbook model of competitive markets (implying that mingling with the wage structure would cause inefficiencies). Due to entry barriers, informational problems, and many other aspects, decentralized markets may be associated with monopoly and monopsony effects which cause wages to deviate from the competitive benchmark model, in particular violating the premise of equal pay for equal work (see Barth and Moene, to appear). A compressed wage structure including minimum wages may also, in the presence of market failures, provide insurance (Dreze and Gollier, 1993, Agell and Lommerud, 1992). Wage setting also involves other aspects related to employment contracts and employment protection legislation.

   Obviously, a compressed wage structure may also reflect concerns for fairness and distributional objectives (see Barth and Moene, 2013). An important issue is the implication of the 'wage floor' created by benefits since it is of crucial importance for those with low qualifications. There is a classical tension between the importance of the wage for those having a job, and its implication for employment and thus unemployment. This has both demand and supply implications.

2. Labor demand: The 'wage floor' matters the most at the lower end of the productivity distribution (the value of the marginal product of labor). Those with low qualifications are thus at risk of being priced out of the market; that is, individuals willing to work might not find an employer because their productivity is below the stipulated wage level. They are involuntarily unemployed. This problem can obviously also arise for business cycle reasons, but the present discussion is confined to structural issues. This may be denoted the demand problem.

   The demand problem is particularly important if trends driven by new technology and globalization tend to reduce the demand for low skilled. This strengthens the dilemma of matching distributional ambitions (e.g., not accepting working poor) with low unemployment for low-skilled.

   Qualifications may depreciate in nonemployment situations; that is, unemployed risk losing qualifications by not maintaining contact to the labor market (depreciating experience, obsolete qualifications, social problems, dwindling network, etc.). As a consequence there may be a path dependence in individual and thus aggregate employment levels, which tends to show up in terms of long-term unemployment (see e.g., Pissarides, 1992).

   The demand problem can in principle be overcome by offering the employer a wage subsidy. However, it is difficult to target such subsidies to the specific individuals facing the above-mentioned barriers, and there is thus a potentially large deadweight loss. Moreover, subsidies are not a solution to the underlying problem created by the lack of qualifications. Therefore, the applied subsidy schemes are usually associated with training requirements.

   The overall demand for labor is obviously business cycle dependent, implying that the strength of the demand problem facing low skilled may vary countercyclically.

3. Labor supply: The basic aim of the social safety net is to cushion income (consumption possibilities) and ensure that loss of job is not causing a dramatic fall in living standard (insurance). Muting the income decrease in case of job loss inevitably implies that the gain from finding a job becomes small (high METR). This is the incentive or supply problem referring to the problem of ensuring sufficiently strong work incentives.
   It is well established that benefits (and additional means-tested supplements for housing, children, etc.) in combination with taxes can cause rather high METRs. In particular cases, they may exceed 100%. Even if this is extreme there is for broad groups a small economic incentive to be active in the labor market (see e.g., OECD, 2012). This raises the pertinent policy question: Does it pay to work?
   The social safety net affects work incentives via the high METRs. This effect does not only relate narrowly to whether people want to work or not, but more widely to how active they are in job search and which types of jobs they are willing to accept. Jobs have numerous characteristics including wages, working hours, qualification requirements, work facilities, work environment, job task, location (transport time/costs), etc. Thus, in most cases the issue is not whether a given individual is willing to work or not, but rather which jobs one is willing to accept and how active one is in job search. A generous social safety net reduces the urgency of finding a job to earn an income.
   It is a concern that reduced job search incentives may lead to permanent benefit dependency by increasing the distance to the labor market for the above-mentioned reasons related to path dependence (see e.g., Ljungqvist and Sargent, 2008). The social safety net was not intended for permanent income support (except for lack of ability to work justifying disability pension) but as a temporary social protection. An important issue for welfare design and reforms is how to maintain short-term insurance without causing a permanent increase in the dependency ratio. (For an overview, see Frederiksson and Holmlund (2006).
   It has been suggested that weak economic incentives to work can be countered by strong work norms, but also that they can be eroded if a sufficiently large share of the population is receiving benefits (Lindbeck, 1995). It may be contested whether strong work norms can be maintained if the economic incentive structure penalizes norm fulfillment.
   Making work pay has featured importantly in recent welfare reforms via earned income tax credits (working tax credit) which may apply to all with a labor income below a certain threshold or be targeted specific groups (single mothers), see e.g., Immervoll and Pearson (2009). The tax credit contributes to make work pay, and in this way strengthens labor supply along the extensive dimension (number of people working). However, to minimize deadweight losses and public finance implications, the tax credit is usually phased out over some income interval, which in turn increases the marginal tax rate, influencing labor supply along the intensive margin. The design of such programs thus involves a trade-off between labor supply along these different margins (see e.g., Saez, 2002).

Tagging or Targeting – Active Labor Market Policy

The above-mentioned discussion points both to qualification and incentive problems as barriers to unemployment. From a policy perspective, the problem is that it is not easy to identify which barrier is binding for a given individual, especially as this may also be state and duration dependent. There is thus a fundamental issue of both targeting (who should be 'treated') and the instrument (which 'treatment').

So-called active labor market policies – also termed workfare, activation, or employment conditionalities – may be a means to address these problems. By active labor market policies is understood that explicit conditions are attached to receiving unemployment benefits or social assistance benefits. These conditions are not requirements to qualify for the benefit, but requirements to maintain it. It is important to note the difference between employment conditionalities and waiting or qualifying conditions. The former refers to conditions associated with receiving benefits; that is, benefits are not provided unconditionally. Waiting or qualifying conditions imply that there are differentiated rights depending on whether these conditions are fulfilled or not. Strong distributional objectives may call the time-consistency of such conditions in doubt. Examples of such conditions include documented active job search, participation in job search courses, education programs, job-training, etc. These conditions are thus different in nature than the eligibility conditions for various forms of disability pensions, where an external health assessment is required. Note that the conditions are two-dimensional involving both the state-of-nature (out of job) and behavioral variables like active job search, participation in education programs etc.

In some countries – in particular the Scandinavian countries – there is a long tradition for using activation requirements in the social safety net, and they have also featured frequently in recent welfare reforms (see e.g., OECD, 2011). These policy reforms have usually been cast in terms of 'rights and duties'; that is, the individual has a right to some benefit if unable to support herself, but also a duty to be active. Oppositely, society has the right to ask the individual to participate in activation programs in return for benefits, but the duty to provide benefits to those unable to support themselves.

To see how active labor market policies may be used to address both the supply and the demand problem note that they may increase the opportunity costs of claiming benefits but also be designed so as to improve the qualifications of the participants.

Active labor market programs thus release a number of effects. Participation in a program may enhance the qualifications of the participants (direct program effect) but also lower their job search during participation (logging-in effect). The increase in the opportunity costs comes primarily via explicit requirements for active job search and the participation requirement. This may imply that certain groups may abstain from claiming the benefit (the screening effect), which makes the system better targeted, and it may imply that reservation

demands for jobs are lowered and job search incentives increased for unemployed (the threat effects), which reduces moral hazard problems. In addition there may be a general equilibrium effect running via wage formation (wage effect) since the outside opportunity for employed is changed if they become unemployed (and eventually participants in an active labor market program).

The political attraction of attaching active labor market conditionalities to unemployment benefits and social assistance is that incentives can be strengthened without necessarily deteriorating the level of support offered by the social safety net. Economic deprivation is not necessary to create incentives! This can also be interpreted in the sense that there is a complementarity between replacement rates and workfare requirements, or that the total package matters in the sense that a given employment level can be supported by either low benefits or relatively high benefits with strong active conditionalities, see e.g., Andersen and Svarer (2014).

Importantly, active labor market policies are resource demanding, and OECD countries spend up to about 1.5% of GDP on such programs. Hence, even though such policies have the attraction that they may work to maintain employment incentives without jeopardizing distributional objectives, this is not coming costlessly.

Two aspects are particularly important in the practical design of active labor market policies, namely timing and program types. Frontloading of workfare requirements will strengthen incentives the most, but it will also be very costly and entail a large deadweight loss from program participation for many who in any case will find a job after a short unemployment spell. This is particularly so in a labor market with a high incidence of short-term unemployment spells. Hence, workfare requirement should be imposed after some duration of an unemployment spell. The group of unemployed is heterogeneous, spanning from some who have the qualifications and experience making them readily employable to some who lack these properties (e.g., due to long-term unemployment) and therefore find it very difficult to get a job. For the former group, help with job search may be sufficient, while for the latter more specific programs may be needed to specifically address the constraints lowering their job finding rate. In some cases, it may be easy to identify these constraints (e.g., if the unemployed lacks specific skills), while in others it may be more difficult and also depend on market conditions (qualifications become obsolete due to structural changes). In the latter case, the avoidance of deadweight losses gives an argument for making workfare programs duration dependent.

These considerations suggest an optimal profile for active labor market policies where the requirements run from general and relatively costless activities to specific and more costly activities, depending on the duration of the unemployment spell. The duration-dependent sequencing of workfare requirements works to minimize deadweight losses and program costs while maintaining the incentive effects and addressing the more specific programs to groups for whom it may make a difference. At the same time it introduces a forward-looking element into the scheme where the stepping up of workfare requirements strengthens work incentives.

There is a vast empirical literature analyzing the effects of active labor market policies. Most of them focus on the direct program effect and the logging-in effect, but some also look at the threat effect. For a recent survey see Card et al. (2010). The general finding is that there is a logging-in effect. Furthermore, it is found that program effects are strongest from private job-training and that there is a threat effect affecting the inflow into benefit schemes. Note that few studies have explicitly assessed the screening and the wage effect.

Active Distribution Policy

The classical discussion of redistribution has its outset in the distribution of market incomes. Is the distribution fair and is there a need for redistribution? However, the distribution of market income is endogenous and dependent on policies, most notably educational policies. Redistribution based on realized marked income may thus be dubbed passive redistribution policy, while educational policy in the broad sense moving in the direction of a more equal distribution of qualifications is an active redistribution policy; that is, it is forming the distribution of market incomes.

Educational policies involve the issue of the general level of qualification of the work force, but the distribution of qualifications is equally important. A main reason for publicly provided education is to reduce the importance of the parents' ability and willingness to pay for education, and in this way to facilitate equal opportunities. The social gradient in education is strong in most countries.

Cross-country data also show that the countries with low income inequality also tend to have low inequality in educational attainments. Countries with extended welfare states like the Northern European countries are also well known for having a substantial public involvement in education, i.e., tax financed and available on a merit basis.

Strong egalitarian preferences rule out working-poor, and thus minimum wages are high. This implies a higher entry threshold in terms of qualifications to find a job. To ensure equal opportunities and to make an egalitarian outcome consistent with a high employment level, it is thus a requirement that the qualification structure is reasonably compressed. To put it differently, it is impossible to maintain a high employment level for a large group of (low) unskilled workers if distributional objectives are ambitious.

It is a well-known fact that the distribution of wages and thus income have become more unequal in recent years, Atkinson et al. (2011). Although the role of various driving factors like technology and globalization is open for debate, the policy issue is how to counteract this. If the premium to qualifications goes up, the immediate response is to shift the supply in the direction of demand. Historically skill-biases in labor demand have to a large extent been counteracted by changes in supply along the qualifications dimensions.

Educational issues are therefore receiving more attention in recent reform initiatives. This applies both to the general level and quality of education, the entry and exit ages from education (including delays, drop-out rates, etc.) and not least the possibilities of reducing the group receiving no or only little education and training of relevance for the labor market. This

involves in particular younger cohorts since it is well known that it is difficult to 'repair' lack of qualifications at a later stage of life. A related policy area is 'life-long' learning to ensure an adaptive labor force.

Concluding Remarks

The frequency of welfare reforms has been high in recent years. This is driven by structural changes and not least demographic changes in combination with strained public finances. Most reforms are parametric or regulatory and rarely involve large systemic changes. Overall policy objectives and hence welfare state arrangements remain rather persistent across countries, but the more specific policy issues and the way to address them are in continuous change.

The informational base for welfare reforms has improved significantly in recent years due to both theoretical advantages in understanding the drivers underlying the fundamental trade-off between insurance and incentives and important empirical advances via the use of microdata and a more systematic use of effect studies as basis for evaluating and designing specific policies.

Welfare Retrenchment

Bernhard Ebbinghaus, School of Social Sciences, University of Mannheim, Mannheim, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Since the economic crisis of the 1970s, welfare state reform is on the political agenda of advanced welfare states facing multiple economic and sociodemographic challenges. The public debate and initial research (in particular, the new politics thesis) focused on the question why welfare retrenchment, the cutting back of public expenditure, has met much public resistance. More recent research studies the variations in welfare restructuring as complex adjustments to multiple challenges, while seeking to explain these changes through compound factors: ideational, institutional, and interest-based explanations.

In public debate 'welfare retrenchment' commonly refers to the restructuring if not curtailment of social policies. Since the economic crises of the 1970s, advanced welfare states have grown to limits facing severe constraints of permanent fiscal austerity and global economic competition. The term 'retrenchment' dates as far back as the British Liberal manifesto of 1906 in referring to avoid an oversized state. During the 1980s it reappeared in public debates on cutting back state activities, in particular public education in the United States, and since the late 1990s, it became more widely used in comparative studies of welfare state reforms (Pierson, 1994).

Most prominently, Paul Pierson claimed that "(t)he politics of retrenchment is typically treacherous, because it imposes tangible losses on concentrated groups of voters in return for diffuse and uncertain gains" (Pierson, 1996: 145). In this view, politicians adopt a 'blame avoidance' strategy by shunning too radical reforms for fear of electoral backlash. This 'new politics' thesis (Pierson, 1996, 2001) has shaped comparative research of the topic (Starke, 2006), becoming a point of reference like Esping-Andersen's regime typology (1990), which also assumed path-dependent institutional inertia. However, there remains much academic debate over the scope and causes of welfare state restructuring (Bonoli and Natali, 2012). Not least, 'retrenchment' is criticized as a too narrow concept for analyzing the cross-national variations of reform capacity and scope. The term focuses merely on cost containment, while there are also more subtle and long-lasting institutional changes that could be described as 'recalibration' (a term used in Pierson, 2001).

Cross-national and case-oriented research has taken different strategies to investigate restructuring of advanced welfare states in The Organisation for Economic Co-operation and Development (OECD) countries. Quantitative studies of welfare retrenchment often tend to measure cutbacks in expenditure, while others also seek to capture restructuring through changes in social rights (both in respect to benefits and services). Outcome-oriented studies evaluate the impact of policy changes on the life chances of social risk groups and the overall level of welfare in a society (for instance, the poverty rate). Politics-oriented studies, both quantitative and qualitative, analyze the processes of reform, in particular the political conflicts involved in changing the status quo in social policies against vested interests. Qualitative policy-oriented case studies investigate which policy instruments are used and how institutional change restructures welfare states: whether reforms are gradual or radical, whether they involve parametric or systematic changes, or whether they have merely short-term or rather long-term impact.

This article focuses on the restructuring, both retrenchment and recalibration, of advanced welfare states since the 1970s. It will first discuss the main external constraints posed by economic globalization and European integration as well as the internal challenges of sociodemographic changes. It then addresses the problem of measuring welfare retrenchment and recalibration by quantitative indicators. The remainder will sketch different theoretical approaches, in particular the new politics thesis as well as theories of institutional change. While the focus of the early literature was on welfare state resilience, more recently, theoretical and empirical analyses turned to how institutional change alters welfare states. While the study of change processes reveals the multifaceted nature of welfare restructuring, the underlying causes need further explanations. Different theoretical frameworks are advanced to explain the mechanism of change: ideas, interests, and institutions. These consider the role of ideas, political institutions, and power relations in welfare state reform processes. The conclusion raises the open research questions and future policy issue is discussed.

Why Are Welfare States in Need of Change?

The 'crisis' of welfare states has been deplored since the economic downturn of the 1970s. While functionalist modernization theory stressed the 'growth to limits' (Peter Flora) of postwar expansion, neo-Marxist accounts saw a 'crises of crisis management' (Claus Offe) that doomed advanced capitalism. The longer unemployment figures ratcheted upward and public debts spiraled out of control, the more the postwar consensus of Keynesian demand-side macroeconomic management became discredited and a 'paradigm shift' toward neoliberal supply side economics took hold (Hall, 1993). Once thought to be the solution to the pressing economic and social problems caused by industrializing economies, since the economic crisis the welfare state has been deplored by its critics as the cause of all problems: an expensive 'nanny state' that fosters inactivity by work disincentives. This neoliberal political turn occurred most

notably in the United Kingdom with the Thatcher government in 1979 and in the United States with the Reagan administration in 1980, both being prime cases of Pierson's (1994) study of welfare retrenchment. Since then the view that welfare states face 'politics in hard times' due to a fiscal crisis of the capitalist state and 'permanent austerity' has become generally shared (Pierson, 2001).

External Challenges: Globalization and European Integration

Welfare states face major challenges, some exogenous through increased international interdependencies and some endogenous through domestic sociodemographic, economic, and political developments (Scharpf and Schmidt, 2000). The economic crisis following the oil shocks in 1973 and 1979 showed the vulnerability of postwar economic growth and its dependence on favorable global 'embedded liberalism.' Since then globalization is seen as a threat to welfare states, not least since the failure of French Keynesianism in one country under the then new Socialist president Mitterrand in 1982. Global competition led to the threat of relocation of production from high labor cost in Western capitalist countries to lower cost countries, first by the Asian Tigers and since the fall of Communism, more widely by emerging market economies. In particular, high labor costs and taxation in advanced economies are seen as major causes of persistent unemployment and low economic growth.

Politically induced liberalization of capital has also increased the threat of tax competition between high-spending welfare states and its leaner competitors. Advanced welfare states have adapted their tax policies by shifting from mobile to immobile taxes, such as tax and payroll taxes as well as value-added taxes (Scharpf and Schmidt, 2000). However, to the degree that welfare states support investment in human capital, foster employment growth, and provide a buffer for open economies, tax competition among OECD countries might not necessarily lead to a downward spiral. Nordic economies, for example, have been capable of combining export-led high-value growth with a social investment strategy financed by high immobile taxes. A social dumping strategy, feared when opening the single European market, has not materialized to the degree that it can endanger welfare state activities. Certainly, the increased importance of international financial markets and the European Monetary Union have made expansionary policies costly and put pressures on nation-states to control if not curtail their public debt. The recent postcrash sovereign debt crisis in Greece, Spain, Portugal, and Ireland has shown that escalating public debt, partly the result of past welfare state expansion, will provide large pressures by foreign debtors to retrench public expenditure.

Within the European Union (EU), political and economic integration also have an impact on national reform processes. The EU limits the capacity of its 'semisovereign' national welfare states to devise their own social policies (Rieger and Leibfried, 2003). The freedom of labor, goods, capital, and services within the European single market increases market pressures, for instance, on social services, while antidiscrimination laws forbid limiting social benefits to citizens, though legal residence requirements are still possible. While the EU requires the transportability of public social benefits for its cross-border mobile workers, it also enforces international competition and market principles in the private provision of social benefits. Nonetheless, the EU or any other supranational organization has only limited competencies in areas of social redistribution as social solidarity remains largely a field of national politics.

Internal Challenges: Demographic and Socioeconomic Changes

Besides these external factors, internal demographic and socioeconomic changes pose further challenges to welfare states; these may be even more important in driving national reform processes (Pierson, 2001). Most importantly, large-scale deindustrialization and the transition to knowledge economies have aggravated labor markets and further accelerated mass long-term unemployment since the 1970s. Not least as a reaction to the employment crisis, expansion of governmental commitments and welfare state maturation expanded access, benefits, and services, yet this has reached levels of welfare state financing that became politically and economically unviable. Thus there are also domestic reasons for soaring public debt and high nonwage labor costs.

The demographic 'time bomb' of aging societies with low birth rate and increasing life expectancy provides a long-term challenge. Aging will increase the costs of pension systems, in particular in pay-as-you-go financed public pensions: ever more pensioners will have to be supported by an ever smaller working population. The EU's old age dependency ratio is projected to double from 26% in 2010 to 53% by 2060. Also, longer life expectancy is seen as a major advancement of functioning health systems and improved public health, the pressures on rising costs for health care and long-term care, particularly for those reaching the Fourth Age with acute risks of physical and cognitive decay. There are also political implications of an ever-older voting population defending their acquired rights, while the small young generation may not have the political clout to overcome intergenerational imbalances.

Further, socioeconomic changes increase the pressure on welfare states in addition to economic downturn following the 2008 global financial crisis. The requirements of today's competitive knowledge society have made those with low skills particularly vulnerable to unemployment and low income. Moreover, changing family, partnership, and household structures require adaptation in various social policies to respond to 'new' social risks. Increased divorce rates have led to a larger share of households with a single parent and children with elevated risks of poverty. More generally, reconciliation of work and family responsibility is needed through a coordination of family policies at communal and workplace level. Continued global migration also remains a challenge to advanced welfare states, requiring social assistance and education policies to enhance social integration and cohesion.

How to Measure Welfare State Change?

Methodologically, the 'dependent variable problem,' that is, the question how to study welfare state change, poses some complexity (Clasen and Siegel, 2007). As Pierson

admits: "Retrenchment is one of those cases in which identifying what is to be explained is almost as difficult as formulating persuasive explanations" (Pierson, 1994: 13). Welfare state restructuring can be studied quantitatively, it can be measured by its output (such as expenditure) and by its outcome (for instance, rise in inequality), or it may also be investigated more qualitatively by the kind of policies undertaken and the politics involved. While an overall perspective based on aggregate data and major principles has been dominant in comparing welfare regimes, changes may occur at varying scope, in different directions, and at specific timing, in particular social policy programs, thus requiring a more disaggregated and policy-oriented analysis.

Public social expenditure is still used as the main indicator for welfare state cutbacks (see **Table 1**), mirroring the earlier modernization studies of welfare state expansion. Commonly used are time series from international organizations, though these are only partly comparable and complete. The OECD Social Expenditure Database, available from 1980 onward, has been the most widely used; it is integrated into the main political indicator series. Eurostat's European System of Social Protection Statistics and the International Labour Organization's Social Security Inquiry also include financing of social expenditure but differ somewhat in detail. To compare social expenditure across time and space, it is common to calculate relative indicators in terms of economic resources (percent gross domestic product), yet changes may then result also from business cycle effects. A comparison across time and major welfare state clusters (see **Table 1**) for longer periods indicates that social expenditure has continued to grow in most countries despite retrenchment efforts since the 1980s, but a rather stable or low growth can be found in the more advanced welfare states. Research has also shown the need to disaggregate these expenditure figures (see contributions in Clasen and Siegel, 2007). Even if there is no decline in overall expenditure, there might be significant changes in its composition, such as from passive to active labor market policy expenditure. Moreover, using social expenditure as a measure of welfare cutbacks may be misleading without taking into account the underlying need, for instance, the rise in aging or unemployment, which increases demand for benefits and services. Thus when social expenditure stagnates in spite of increasing demand, benefits and services will be on average at a lower level unless there are efficiency gains.

Further problems abound in using readily available social expenditure data. Thus only member countries of international organizations, such as OECD or Eurostat, will be considered for international comparison, limiting the set of comparable cases. A particular difficult issue is the inclusion of mandatory and if possible voluntary private expenditure in order to compare the shift from public to private responsibility. Taxation can also claw back social benefits, and taxing of social benefits varies across countries and over time. According to alternative OECD statistics that also include private expenditure and the net benefit effect, the differences between Nordic high spending and the United States as low spender are much narrower than the public gross social expenditure figures suggest.

Studying Changes in Social Rights

Expenditure as a measure of welfare state activity has been heavily criticized, most prominently by Esping-Andersen (1990: 21): "It is difficult to imagine anyone struggled for spending per se." Instead, he stressed the importance of studying social rights, in particular whether social rights are 'decommodified,' that is, benefits are granted independently from the market. For instance, a shift toward greater equivalence between contributions and benefits would indicate recommodification. A major indicator is thus the replacement rate of unemployment, old age, disability pension, or sick pay benefits in relation to past earnings. But the provision of services, for instance, measured by the size of the public sector employment, could be an indicator of welfare production. Indicators for welfare outcome are the prevalence of poverty, inequality, or nonemployment or other indicators of social exclusion (e.g., the EU's Laeken indicators).

More qualitative considerations of social rights and duties study the changing conditions attached to benefits and services. An example is the reliance on benefit conditionality, for instance, active job search requirements for eligibility of unemployment assistance, which stipulate in case of noncompliance sanctions such as the partial or full withdrawal of benefits. Thus the introduction of 'workfare,' tying benefits to activation measures, has been a hallmark of the paradigm shift in labor market policies, particularly in Liberal countries.

Table 1 OECD social expenditure percent gross domestic product, averages 1980–2013

	1980–89	*1990–99*	*2000–07*	*2008–13*	*Growth index*
Continental Europe (1)	22.2	23.8	24.5	25.9	116.9
Southern Europe (2)	15.7	18.9	21.7	25.5	162.9
Eastern Europe (3)	–	19.9	18.9	20.5	–
Nordic Europe (4)	23.1	28.0	25.9	27.4	118.7
United Kingdom	18.4	19.1	19.8	23.5	127.9
Liberal overseas (5)	15.3	18.1	17.4	19.3	126.7
United States	13.4	14.9	15.8	19.2	143.5
Japan	11.1	13.4	17.8	21.5	194.3
OECD total (6)	16.8	19.2	19.5	21.6	128.2

Notes: Index 2008–13 (100 = 1980–89); Country averages: (1) Austria, Belgium, France, Germany, Luxembourg, Netherlands, Switzerland; (2) Greece, Italy, Portugal, Spain; (3) Czech Republic, Estonia, Hungary, Poland, Slovak Republic, Slovenia; (4) Denmark, Finland, Norway, Sweden; (5) Australia, Canada, New Zealand; (6) OECD total includes all member countries.

The retreat of the state from public provision has also led to an increase in private responsibility; therefore, changes in the provision, governance, or regulation of social protection are of importance in understanding welfare state restructuring. However, statistics on the public–private mix in social protection are difficult to obtain and often depend on legal definition, thus even the OECD publishes different statistics depending on the particular publication or database. For instance, in pension policy, collectively negotiated pensions are counted as mandatory (quasi-public) pensions in some statistics, while as private-funded pensions in others.

New Politics Thesis: Welfare State Resilience through Policy Feedback

The new politics thesis claims that welfare state restructuring in times of austerity differs from reforms during the golden age of expansion. While the extension of social rights allowed credit claiming, in times of fiscal constraints politicians face the hard choice of pursuing unpopular measures, which may lead to electoral defeat. Comparing the politics of retrenchment under Reagan and Thatcher, Paul Pierson (1994) claimed that policy feedback led to a surprising resilience of welfare states, observing no overall retrenchment despite its rhetoric. Indeed, politicians would be reluctant to reform since "cutbacks generally impose immediate pain on specific groups, usually in return for diffuse, long-term, and uncertain benefits" (Pierson, 1994: 18). According to prospect theory, voters are risk averse in respect to future gains, but react more severely against current losses. Given this 'negativity bias' (Pierson, 1996), politicians seek strategies of 'blame avoidance' for fear of upsetting voters.

Whatever the fiscal challenges, welfare state retrenchment remains largely unpopular. Past social policies have led to a strong policy feedback in creating a large popular support from below for all those benefiting from welfare state policies: current and potential beneficiaries as well as public sector employees. Comparative research on public attitudes time and again and largely across very different systems has shown the high popularity of welfare states as a major factor for its persistence. In particular, the role of government in guaranteeing social benefits in old age and providing health services is very popular since all expect to profit from it, followed by programs for families with children. But programs for the long-term unemployed and minimum income schemes for the poor are somewhat less popular since these depend on perceptions of deservingness. Thus in respect to public opinion, the distribution of benefit and costs, the degree of universality of benefits, and the nonconcentration of costs matters for widespread public support.

According to the new politics thesis, politicians pursuing blame avoidance strategies can use several instruments (Pierson, 2001): obfuscating, divisive, and compensatory strategies. The strategy of obfuscation (Pierson, 1994: 22) includes gradualism, which is a stepwise transition instead of sudden changes, such as 'grandfathering' rules exempting current pensioners and senior workers from pension reforms, while affecting future cohorts that retire later. Other forms include technocratic regulation or automatic adaptation mechanisms so that politicians are not held directly responsible. For instance, the Swedish pension reform of 1994 introduced an automatic adjustment of benefits to demographic and economic changes. In addition, burden shifting onto other actors, for instance, from central to local governments or from state to private actors could dilute responsibility. Moreover, strategies of 'divide and conquer' could be used to split opposition. For instance, the UK government sold off public housing to current tenants, while cutting back on new social housing projects to accommodate future people in need (Pierson, 1994). Finally, compensation could be used to combine the extension of social rights with cutbacks of current benefits, thus also using 'credit claiming' strategies (Bonoli and Natali, 2012), for instance, cutting back pension benefits for those without work-related contributions but introducing credits for work interruptions for mothers with children. Indeed, politicians might be able to claim credit for such 'vice into virtue' politics, rebalancing the intergenerational contract.

The central argument of the new politics thesis is that politicians are vote seekers; they pursue blame avoidance because they fear electoral backlash. This is particularly the case in two-party systems and first-past-the-post electoral systems. Yet politicians might be also policy seekers; they are ideologically predisposed in favor or against welfare retrenchment, or they see reform pressures as too large to avoid blame. In fact, unpopular and far-reaching reforms have been occasionally undertaken, and this may not always have led to electoral backlash, particularly not if there were few alternatives available. Studies on the consequences of welfare reforms on electoral politics show a rather differentiated picture. Cross-national comparisons show that conservative parties (religious and neoliberal parties) pursue welfare retrenchment by attempting to claim credit among their voters with some success, while left-wing parties claim credit for social investment policies, particularly in Nordic countries.

Reform Dynamics through Ideational and Institutional Change

Claims of a 'frozen' welfare state landscape by Esping-Andersen (1990) and institutional inertia due to policy feedback by Pierson (2001) are challenged in the more recent literature on institutional change. The all-party consensus on the far-reaching pension reform in Sweden or the paradigm shift toward activation in Danish labor market policy were such examples in the 1990s. Even in the least likely case of Conservative welfare states, 'path departures' have been observed across Continental Europe (Bonoli and Natali, 2012). For instance, the Italian pension reform of 1995 led to the major phasing out of previously generous pension arrangement or the 'Hartz IV' reform of 2004 merged unemployment and social assistance in Germany.

Analytically, institutionalist theory moved from a concern about explaining institutional stickiness to explaining path departure or 'regime change' (Weaver, 2010). After parametric reforms have had only limited effect, more radical welfare state reforms led to systemic changes: transforming the basic principles, altering the instruments, and converting the goals of welfare policies. An important impetus for systemic reforms is

negative feedback, these are "consequences of policy that tend to undermine rather than reinforce the political, fiscal or social sustainability of a particular set of policies" (Weaver, 2010: 137). An example of such a vicious circle is the Continental dilemma (Scharpf and Schmidt, 2000): the spiral of increased labor costs through high payroll taxes that drive labor out of work, leading to passive labor market policies such as early retirement, which then drive social security costs further up.

Ideational accounts have been first applied to the paradigm shift from Keynesian to neoliberal economic thinking (Hall, 1993). Ideas could influence the framing of the problem situation, the alternatives available, and the preferred solution. For instance, the EU's Open Method of Coordination is a political process that relies on peer review and learning from others as instruments to cross-border exchange of ideas. While ideational mechanism in the form of learned and shared cognitive scripts plays a role in ordinary situation, more ideologically loaded world views may be activated in a crisis situation where much is unknown. The role of discourse in policy communities, scientific circles, and public opinion have been studied, revealing various strategies of framing debates on the need to reform and the way of reforming. Adopting a discursive institutionalist perspective (see Schmidt in Scharpf and Schmidt, 2000), various case studies have looked at the importance of public discourse and ideational framing has been studied for welfare state reforms. Analytically and empirically, it remains an open question how new ideas diffuse and gain dominance so that they significantly affect the politics of reform and social policy initiatives. Since discursive framing can be used as a political strategy by politicians and interest groups, the dominance of paradigms or the conflict of ideas points ultimately at political factors.

Recent contributions to understand institutional change have led to taxonomies of different change processes, exemplified by historical case studies often drawn from welfare state reforms (Streeck and Thelen, 2005): layering, conversion, and policy drift. The strategy of institutional 'layering' creates a new institution in addition to existing ones, for example, in Germany, the Riester reforms in 2001 and 2004 introduced voluntary personal pensions beside public pensions, which decline in income replacement capacity. The next process is called conversion, the change of the goal or function of an institution; in the German case the Bismarckian pledge to maintain past living standards is given up and public pensions increasingly can only provide a minimum income in old age. While many changes are induced by public policy, welfare state transformation is often the result of policy drift: the nonaction of governments allows deviations on the ground from the functioning of the system. For instance, the rather silent withdrawal of employers from their defined benefit schemes in favor of less costly defined contribution schemes in the United States and the United Kingdom is such a subterranean transformation.

Welfare Restructuring and Political Institutions

Institutionalist political analyses of reform processes highlight the importance of institutional 'veto points' for interest groupings in influencing if not blocking social policy reforms. Ellen Immergut (1991) showed in a comparative study the varying leverage of veto points in the political systems for the medical professions to influence health care policies. Depending on the concentration or fragmentation of political power in political system in general and the specific policy area, governments have more or less possibilities to alter the status quo. In particular, institutional differences between majoritarian and consensus democracy, and between centralized and federalist polity, and the role of constitutional courts have been singled out. Using institutional veto point indices, comparative studies explored whether systems with more (or less) institutional veto points provide a break (or accelerating) impact on welfare retrenchments (Huber and Stephens, 2001).

More formal political theory focuses on the role of veto players, of individual and collective as well as partisan and institutional ones, in changing the status quo. Reform coalitions depend on the cohesion and congruence of the veto players; the lower the congruence and the higher the cohesion of veto players, the more unlikely is a change of the status quo. While during the expansionary phase a system with many veto players may have slowed down social expenditure, it will provide a break on welfare retrenchment. However, veto player analysis is less amenable to comparative analysis of welfare state development than veto point indicators, but requires more detailed policy case studies that explore the positions and properties of veto players.

Welfare Restructuring and Power Relations

Political-power-related explanations have been the hallmark of explanations of postwar welfare state expansions, but they also help to explain shifts in political coalitions supporting or opposing welfare state retrenchment or restructuring. Clayton and Pontusson refute the new politics thesis: "Societal interests and coalitional alignments have changed, but there is no need to invent a new set of analytical categories in order to explain current patterns of welfare-state retrenchment or restructuring" (Clayton and Pontusson, 1998: 98). Thus institutional change of welfare states can be explained by changing power relations and interest coalitions. While Pierson assumed that "the centrality of left party and union confederation strength to welfare state outcomes has declined" (Pierson, 1996: 151), several critics have challenged this view and stressed that old politics, that is, class conflict (Korpi and Palme, 2003) and the strengths of organized labor, still matters.

Conflict theoretical perspectives, most prominently Korpi's power resource approach, has maintained that left (working class) parties and allied trade unions do not only matter for the postwar expansion of welfare states but also for welfare state 'regress' in times of austerity (Korpi and Palme, 2003). Welfare state retrenchment is seen as a remaking of the postwar societal contract to maintain full employment for which partisan politics and welfare institutions matter. Analyzing the decline in net replacement rates of (short-term) social benefits and the number of benefit cuts across OECD countries (1975–95), Korpi and Palme find that partisan government, welfare state institutions, and constitutional veto point matter in addition to globalization and postindustrial development. Welfare

retrenchment is least likely under conditions of left-wing cabinet participation, encompassing welfare states, and corporatist institutions.

In the debate on the impact of globalization on welfare state development, several political economists (Garrett, 1998; Rieger and Leibfried, 2003) argued that welfare states particularly in 'small' economies were expanded in compensation for opening up domestic economies, and that this compensation is still maintained in times of globalization. Comparative research, both quantitative pooled time series and qualitative case studies, showed that social democratic welfare states have been proved to be highly resilient (Garrett, 1998; Scharpf and Schmidt, 2000; Huber and Stephens, 2001). Others argued that social democratic governments would also reform welfare policies, but that these changes would seek a 'new third way' of employment-friendly social investment policies between neoliberal retrenchment and socialist expansion. Major reforms leading to a paradigm shift in labor market policies were enacted under left party participation in the government in Europe, such as the Danish 'flexcurity' and Dutch activation policies in the mid-1990s as well as the German 'Hartz IV' reform of 2004.

Corporatist analyses also pointed at the fact that trade unions have been successful in blocking major reforms through mass protests if not strike action, most notably the pension reforms in Italy in 1994 and France in 1995. To avoid blockage, some governments have sought to negotiate welfare reforms with the social partners, leading in a few cases to far-reaching 'social pacts,' particularly in the run up to the introduction of the Euro (Avdagic et al., 2011). Instead of the old corporatist exchange of wage moderation in return for an extension of social rights, supply side 'competitive corporatism' in times of austerity entailed that unions could influence the process of restructuring but needed to accept some changes of the status quo. Such corporatist concertation, however, remained highly contingent on the willingness and capacity of governments, employers, and unions to strike a deal that could lead to a positive sum outcome for all.

Outlook

Welfare retrenchment, or the conceptually more open welfare restructuring, has been an emerging topic of public debate and scientific analysis. The welfare state as we know it has been considered under attack since the economic crisis of the 1970s. The economic and sociodemographic challenges have been long known, yet readjustments of welfare states were slow in meeting the requirements of globalization and fiscal austerity as well as the changes brought about with an aging society, modern social relations, and knowledge-based societies. While the welfare state remains highly popular and politicians may fear electoral backlash against welfare retrenchment, the need to readjust social policies cannot be denied. Indeed, multiple short-term parametric and also noteworthy long-term systemic changes have been enacted across OECD countries. The financial crash of 2008 and the subsequent sovereign debt crises have indicated that welfare state restructuring if not retrenchment remains on the political agenda. The political costs of inaction may be in the long run as big as those short-term electoral losses for undertaking unpopular reforms. What seem to be missing in recent years are efforts to find broader political and societal consensus on the direction and scope of welfare state restructuring, as had happened in some social pacts in the 1990s.

The current development of research indicates that the dependent variable, the methodological approaches, and explanatory frameworks have become more differentiated. In order to understand the complex process of welfare state restructuring, more detailed specialized studies are needed on different social programs, the public–private mix, the conditions of social benefits, the quality of social services, and the welfare outcomes. However, this has led to a rather bewildering puzzle of confirming and contradicting findings. Moving away from the single theoretical framework of the new politics thesis, alternative explanations are now available across a wide field of ideational, power interest, and institutionalist approaches, albeit without much theoretical integration. Although the phenomena under study has been observed for over three decades, our knowledge about the causes, conditions, mechanism, and outcomes of the dynamics of welfare state restructuring in times of permanent austerity has been still scattered. More systematic synthesis of empirical findings and explanatory successes is needed to allow more forward-looking policy recommendations. In any case, the need for and efforts toward welfare restructuring will stay for a long time to come.

Abstract

In England, the term 'welfare state' dates from the 1940s. It has stronger associations of paternalism in American English. How is 'welfare state' translated into German? Conflict exists between the terms and *Sozialstaat*. The definition as per Briggs is influenced by the events of the 1940s. The history of the 'Origins of the Welfare State' is illustrated by two versions, the British and the German, that indicate differences in periodization and focus, and suggest the influence of political considerations. A brief reference to the Swedish version illustrates the same point. A general history of 'the welfare state,' as distinct from the history of individual welfare states follows. Is it located in the wider context of the history of the state? Points considered are unification of the law, establishment of bureaucracies, elimination or control of intermediate forms of authority, and its characterization by new systems of domination peculiar to it. The role of representative democracy is also considered. The connection with the development of industrial capitalism is analyzed in terms of the problem of 'externalities' as well as the role of combinations and transfer payments, of public provision of goods and services, and of regulation. The history of welfare states since 1945 with a few generalizations is followed by a look at the effect of major changes in the international economy. The article concludes with an examination of recent influences on the historiography of welfare states such as a gender-conscious historiography, welfare state history 'from below,' studying the 'mixed economy of welfare,' and comparative studies.

The Origin and Use of the Term Welfare State

The term was coined in England in the 1940s. It is to be found in *Citizen and Churchman* (1941) by William Temple, Archbishop of York, where it is contrasted with the Power State or Warfare State. After the publication of the Beveridge Report in 1942, the term soon came to be applied to the hopes for postwar reconstruction and by 1948 was used regularly for the postwar reforms. The meaning of 'welfare' had not suffered the deterioration that had afflicted the word 'charity.' Although Beveridge himself disliked the term for what he called its 'Santa Claus' connotations and preferred the older term 'social service state,' 'welfare state' normally carried a favorable meaning.

Welfare had a different set of connotations in American English. 'Public welfare,' as understood in the United States then and since, excluded the elements of social insurance, with its claims to benefit as of right, which were so prominent in the British construction of the term (Lindeman, 1937). 'Welfare state,' once imported from Britain, thus carried a stronger association of paternalism (Skocpol and Ikenberry, 1983).

In that respect, Germany was closer to the United States. In the early years of the Federal Republic, when many English terms were naturalized into German, it seemed natural to render 'welfare state' with the similar word *Wohlfahrtsstaat*. Such similarities can be misleading. *Wohlfahrt* was associated with charitable gifts, and *Wohlfahrtsstaat* had acquired a pejorative connotation during the crisis of the Weimar Republic, as when in 1932 Chancellor von Papen accused politicians of the early years of the Weimar Republic of attempting to turn the state into a *Wohlfahrtsstaat*, and thereby weakening the moral strength of the nation. The Federal Republic wished to return to the Weimar tradition in social policy without falling foul of the associations of the term *Wohlfahrtsstaat*. One possible course was to use the term in its positive English sense and to resort to *Versorgungsstaat* to convey the pejorative meaning. The alternative was to revive a nineteenth-century term, *Sozialstaat* (Ritter, 1989). The issue has never been settled decisively, although *Sozialstaat* is the more usual.

If the term dates from the 1940s, its definition also owes much to the changes of that period. According to Asa Briggs, "A welfare state is a state in which organized power is deliberately used (through politics and administration) in an effort to modify the play of market forces in at least three directions – first by guaranteeing individuals and families a minimum of income irrespective of the market value of their work or their property; second, by narrowing the extent of insecurity by enabling individuals and families to meet certain "contingencies"…; and third, by ensuring that all citizens without distinction of status or class are offered … a certain agreed range of social services" (Briggs, 1961). These are usually taken to relate at least to medical treatment, housing provision, and education. Briggs added a reference to the best standards available, but it has since been generally accepted that such an aspiration is unrealistic.

The 'Origins of the Welfare State'

Such an emphasis on the 1940s leaves the historian with the task of relating these innovations to what had gone before, i.e., to consider the 'origins of the welfare state.' Three national examples briefly indicate how differently the origins of the welfare state have been constructed.

British Historiography

Since 1961, this has operated in terms of the transformation of old institutions by new principles, forged at moments of political crisis (Fraser, 1973). The first of these institutions was the Poor Law, which established the responsibility of each local parish for the relief of the poor (1603) and was reformed in 1834 on more explicitly deterrent lines in response

to population growth and agricultural change. The subsequent history has been presented in terms of new social problems caused by industrialization, the Victorian origins of collectivism in public health and factory regulation, the crisis of the Poor Law at the end of the nineteenth century, and the consequent Edwardian legislation (1905–14). This put an end to the possibility of a gradual extension of Poor Law services on a nondeterrent basis and provided for needy and deserving groups in other ways. It introduced free school meals, a school medical service, tax-financed old-age pensions for the poor, and national health and unemployment insurance, supported by a national network of labor exchanges. Alongside these measures, 'New Liberalism' articulated a theoretical justification for state intervention in society and economy. The scope of this legislation was limited in respect of population covered and of benefits provided, but it has been regarded as having laid 'the foundations of the British welfare state.'

The interwar years saw housing provision added to the prewar measures, but social policy responded slowly and piecemeal to economic and social problems. It adapted rapidly once World War II had created new problems and a new spirit of citizenship. The postwar legislation, roughly but far from exactly based on the proposals of the Beveridge Report (1942), universalized national insurance, extended its benefits to cover a greater range of contingencies ('from the cradle to the grave'), and established a mainly tax-financed national health service. This was accompanied by tax-financed child allowances, the extension of housing provision, and free secondary education. Fundamental was a government commitment to a policy of full employment, based to some extent on a belief in the efficacy of Keynesian demand management that was, however, far from unequivocal. The transformation of old social services by new principles of universalism had been presented in the Beveridge report as a characteristic British revolution. Historians followed a similar line, which fitted into the then dominant 'Whiggish' historiography with its emphasis on the continuity of British history and the adaptability of its political leaders. In the influential view of the sociologist T.H. Marshall, the welfare state had achieved the extension of citizen rights from civil rights via political rights in the past to a new body of social rights (Marshall, 1950). The blueprint of the welfare state as established in the 1940s was for a long time presented as a major British contribution to postwar social reconstruction in the wider world.

German Historiography

This has located the origins not merely of its own welfare state but of the welfare state as such in the establishment of compulsory insurance for workers by the German Empire under Bismarck in the 1880s. It has both emphasized the pioneering role of Germany and the continuity of its insurance institutions despite drastic political change. This emphasis on the role of Bismarck, notorious for his hostility to the claims of the working-class movement, as the originator of the welfare state has presented historians with the problem of reconciling these two aspects of his policy. Until recently, it was suggested that wooing the workers with the benefits of social policy was an intrinsic aspect of Bismarck's attempt to suppress social democracy. This view had the merit of presenting the welfare state as the achievement of the democratic forces while recognizing that the policies usually were not what these had been demanding. The publication of documents on Bismarck's social policy has cast doubt on this view of his aims and there is a need for reinterpretation (Tennstedt and Winter, 1993; 1995).

The transition from the establishment of institutions with limited scope to the conscious acceptance of the people's welfare as an essential object of the state is located by German historiography in the Weimar Republic. It found expression not only in the text of the constitution but also across a range of its institutions, several of which had developed from war-time innovations. Collective bargaining backed by compulsory arbitration, subsidized housing, the preservation of prewar social insurance for both blue- and white-collar workers, and unemployment insurance as part of labor market policy, all suggest that the Weimar Republic was a welfare state in deed as in word. In German history, the breakthrough to the welfare state was therefore achieved not after World War II but after World War I. However, the Weimar welfare state was unable to live up to its expectations (Abelshauser, 1987). The political acceptance of its new role was insufficiently broadly based. As the earlier quotation from von Papen suggests, repudiation of the Weimar Republic in the years of economic crisis was connected closely with its social policy.

Although marginalized and only just saved from drastic changes in 1942, the social insurance system survived the Nazis. In the immediate postwar years of economic ruin, forced migration, and impoverishment, it faced perhaps its greatest test. All accumulated funds had been lost. In the Russian zone of occupation, it was reconstructed radically along lines originally proposed by the left-wing critics of Weimar policy. It was no more sacrosanct in the West. The French quickly followed the Russian example. Drastic British proposals followed, based partly on Social Democratic ideas from the Weimar years, partly on Beveridgean lines. They involved retrenchment and thereby aroused opposition well beyond the threatened vested interests. Opposition rallied around the defense of the Bismarckian inheritance in social insurance, which was presented as one of Germany's proud contributions at a time when the nation badly needed a boost to national self-esteem. With the onset of the Cold War, the proposals were dropped as the Western occupation powers gave priority to working with German public opinion. It was left to the Federal Republic to deal with the problems of funding social security; under CDU leadership the traditional structures were almost completely reinstated. Significant reform was delayed until 1957. In that year, the introduction of the 'dynamic' pension, linked to average wage levels, represented an imaginative response to the problems of the Federal Republic, not just the problem of inflation but also that of the low pension levels, which contrasted sharply with the rising standard of living enjoyed by the working population. At a time when the legitimacy of the Federal Republic was fragile, this pension reform contributed significantly to the acceptance of the regime. In 1958–61, proposals to remodel the sickness insurance system and contain its spiraling costs were defeated. The Bismarckian prototype had acquired a secure political profile.

Thus, in the German Federal Republic the 1940s was a period of defense and restoration. The emphasis on the

significance of the Bismarckian reforms for the long-term development of the German welfare state and the tendency to identify it narrowly with contributory social insurance were forged in the political conflicts of those years. This emphasis was reinforced in the early 1980s by the centenary celebrations of the Bismarckian reforms. Much of the German historiography of the welfare state was created in the 1980s (Ritter, 1983, 1986, 1989).

These examples indicate that the history of the welfare state has been perceived differently in different countries, in terms of periodization and of emphasis. This reflects not only its actual development in different states but certainly also the political purposes that historiography has served.

The Swedish Model

These points must be made more briefly for the influential Swedish model of the welfare state. There, it was developments in the 1930s that had the significant long-term effects that they singularly failed to have in Britain or Germany. The expansion of the earlier limited social security provisions took a significantly different form. Unlike Germany, where insurance contributions and benefits differed according to levels of income, Swedish benefits were paid, as in Britain, at a flat rate for all. But they differed from both the German and the British provisions in that retirement pensions and sickness insurance were financed from general taxation. They were set at a level that provided pensioners with an adequate income, something that the British pensions, tied to contributions that even the lowest paid could afford, entirely failed to do. Significant differences between the policies of these three welfare states also extended to industrial relations and taxation.

The Swedish welfare state has been presented as the achievement of class mobilization and labor solidarity. Standard accounts have stressed the long period of Socialist-dominated government and cooperation between government and labor organizations in the shaping of labor market policies (Baldwin, 1990).

A General History of 'The Welfare State'

If it exists at all, the history of the welfare state, as distinct from the history of individual welfare states, must be sought on a higher level of generalization. A welfare state is a state of a certain kind, distinguished from earlier kinds by the addition of a new set of objectives and institutions. Its history must be sought within the wider context of the history of the state. It presupposes the unification of law across the state territory, the establishment of bureaucracies, and the elimination or control of intermediate forms of authority. It is, however, also characterized by new systems of domination, consisting of distributing elites, service bureaucracies, and social clienteles. The process by which these objectives were both established and extended to include the whole nation has been driven by the advent of representative democracy, and it also drew on older concerns to maximize the human resources of the state. In addition, these new state objectives have been connected intimately with the development of modern industrial capitalism.

The state became a welfare state because it dealt increasingly with the social consequences of the particular way in which modern industrial capitalism was established. These consequences, often described as externalities, resulted from the narrow definition of the legal obligations of capitalist entrepreneurs, which contrasted greatly with the obligations imposed on entrepreneurs in the older corporatist economy. This emancipation of the entrepreneur was a deliberate act of state policy, undertaken in the interest of increasing 'the wealth of nations' and thus the power of states over against other states. It undoubtedly had that effect. Enterprise took new and unforeseen forms once it was freed from old regulations. To limit obligations toward workers to the short-term purchase of their labor power, toward the community to the payment of local taxes, and to resort to competition without responsibility for those driven out of the market, all this encouraged innovation and facilitated capital accumulation. But it created problems that resulted from economic decisions while being external to the economic process.

Combinations and/or Transfer Payments

These problems could be dealt with in at least two ways. (1) By combination, intended to limit free competition over wages, or to pool the economic resources of individuals, or both (trade unions and mutual aid societies). To what extent that was possible depended on the attitude of the state and on the capacity of individuals for organization. (2) By state action in whatever territorial units – national, provincial, or local – it exercised its power. That meant taxation and a limited redistribution of the resources originally distributed by the market. The administrative capacity that made it possible to introduce graduated taxes and differential tax allowances as instruments of redistribution is an important aspect of this history.

The legalization of combinations to increase wages in turn made it increasingly possible for individuals to satisfy their needs through the market, thereby creating opportunities for new kinds of enterprise. The legalization of mutual aid associations created structures of redistribution, which could operate as alternatives to the bureaucratic structures of the state. In countries in which the development of bureaucracy had not advanced far, or where it was viewed with mistrust, subsidies from taxes became a way of making mutual associations more effective. Such subsidies were not unconditional but subjected the association to a greater or lesser degree of control. An extreme example of such control was the compulsory establishment of combinations on the order of the state, such as the German sickness funds and trade associations to administer accident insurance. The higher the level in the administrative hierarchy on which the state operated to redistribute resources, the greater the degree of uniformity it could impose.

Goods and Services

So far, the focus has been mainly on the redistributive role of the welfare state. The problem of externalities has also been addressed by the public provision of goods and services, which the market supplied only in ways deemed politically unacceptable. Such goods and services, considered necessary for the common good as politically defined, have included the

infrastructure of public health, the provision of healthy and environmentally approved housing, of medical treatment, and of schools, but this list is far from exhaustive. Here, too, subsidies could take the place of full state provision, e.g., in respect of houses, food, or schools.

Regulation

Since externalities had been allowed to arise because the state had regulated the conditions of production in minimal ways, it also began to introduce new regulations. Under such regulations, the market was permitted to supply goods and services only on conditions acceptable to the state. Instead of providing housing, the state regulated the conditions of tenancies. Instead of running its own schools, it regulated and inspected those provided by other bodies. And, as in Thatcherite Britain, it regulated the sanitary infrastructure while relying on the market to provide it. Such regulation could be accompanied by subsidies. However, such regulation suffers from the same considerations that applied to the general conditions of production in the first place. By regulating the actions of the market, the state is liable to hinder innovation and to make the market an inefficient mechanism for economic growth.

Finally, the state has been able to regulate the economy itself in such a way as to minimize externalities. Examples are the state regulation of wages and the regulation of the economy so as to reduce cyclical fluctuations. At all stages of this process, the question has to be faced whether the object is being achieved at the cost of economic innovation and efficiency. For that reason, there are limits to what regulation can achieve.

A radical alternative has been for the state to take over the running of the total economy. That rules out a welfare state, defined as a state that modifies the play of market forces, and it creates a state so different that it is better not to describe it as a welfare state. That is not to deny, however, that 'communist' states provide social services and organize transfer payments in the interest of social security. This article does not deal with the history of states with a command economy, confining itself to the history of what is sometimes called the liberal welfare state.

Even there the importance of the welfare elements of the state can vary according to the extent to which entrepreneurs did in practice externalize their costs. Where company welfare was built into the entrepreneurial ethic, as in Japan, state expenditure on social security has been restricted compared with other advanced industrial countries.

The History of Welfare States since 1945

Despite this attempt and others (Flora and Heidenheimer, 1982) to construct explanatory models of the welfare state as a general phenomenon of European and subsequently extra-European history, the established tradition of nation-state history has led historians to study developments both before and after 1945 in terms of individual states. They have given prominence to the political circumstances under which social policy was constructed and emphasized the importance of national traditions.

Some few generalizations across countries are feasible. Thus, the experience of the 1930s had demonstrated that institutions of social security were seriously vulnerable to periods of mass unemployment. Such periods greatly increased the demands for transfer payments, while also reducing the income from which these were made. This was particularly true of contributory insurance, and it also applied to finance from general taxation. This lesson had been learned, and in the 1940s, macroeconomic policy became a policy component of every state, whether it had passed through the experience of a war economy or, like Sweden, had not. In some countries, this period saw major reforms and extensions in social security, as in Britain, France, and Sweden. In others, major reforms had to wait until the 1960s and early 1970s after the restructuring of the economy had yielded its rewards, as in The Netherlands and Italy.

Even where significant legislative innovation occurred in the immediate postwar years, subsequent expansion of the economy provided the setting for a period of further change in the 1960s and 1970s. Indeed, the most convincing historical generalizations that can be made about the welfare states since 1945 refer to the effect of major changes in the international economy. A long period of economic recovery in Europe led by the 1960s to a remarkable growth in national income. This in turn both raised expectations and facilitated the introduction of more generous provisions. Levels of benefits were raised, flat-rate pensions complemented by graduated ones that mirrored differences in original earnings and appealed to the better off, while those disadvantaged by or excluded from earnings-based insurance systems received compensatory entitlements.

By contrast, the setback to economic expansion in the mid-1970s, triggered by the oil price crisis, caused a fall in employment, except where special measures for job creation had been implemented (as in Sweden). This, in turn, led to rises in social security payments and falls in the revenue available for the purpose. Steady increases in the gross national product, which had spurred ambitious changes in entitlements in the previous decade and a half, could no longer be assumed. Nor had recent rapid growth in social expenditure been due only to deliberate changes in entitlement. It had also been caused by such demographic, cultural, and technological changes as an increase in the proportion of the elderly, a rise in single-parent families, and the growing cost of medical treatment. To the fiscal crisis that occurred in every country sooner or later, even in Sweden, was added a crisis of belief in the assumptions on which welfare states had been based. Yet these assumptions had been deeply implanted in the citizens, and many vested interests created. Measured by the radical debate that broke out, the actual changes in welfare states were not great, even in Great Britain, where the call for the rolling back of the state had been loudest.

Historiography of Welfare States

There are several ways in which the original traditions of welfare state history have been modified.

A Gender-Conscious Historiography

Just as the feminist movement has since the 1960s exerted a political influence on the agenda of policy making itself, so

it has also changed historical perceptions. Feminist historians have highlighted the way in which social policies were shaped by assumptions about the gender divisions of labor, power, and social responsibility. They have shown how little the basic assumption that each adult woman was dependent on a male earner was borne out in reality. Contributory insurance, with entitlements dependent on the performance of waged labor over most of the adult life span, had been at the center of welfare state history. It looked very different through the eyes of feminist historians, but these have not merely confined themselves to criticism. By drawing attention to policies in support of motherhood, they have reconstructed the outlines of welfare state history (Pedersen, 1993; Koven and Michel, 1993). By making historians more aware of the implications of gender, this emphasis has yet unrealized potentials. Male roles, once so taken for granted as to be largely invisible to historians, have in turn become objects of historical study.

Welfare State History 'from Below'

The history of social policy traditionally has been written through the eyes of 'policy makers' and administrators, and occasionally of political philosophers, trade union officials, and radical politicians, authority figures all. Welfare state history has been particularly resistant to the search for history as experienced by those without power and influence. Yet the construction of social policy and its administration is that of a relationship, in which the recipients of 'benefits' are at least half the story. Like all forms of history from below, attempts to recreate their experience has been hindered by their inarticulacy, at least in forms that have survived as records. But once historians search, they are able to find evidence, not merely for recent times but also at least in England going back well into the past (Lees, 1998; Vincent, 1991).

Studying the 'Mixed Economy of Welfare'

One result of paying more attention to the lives of the poor has been to downgrade the importance of state provisions and to draw attention to the mixture of resources that made up the economy of the poor. Since public authorities frequently did not intend to provide those in need with a full subsistence – and, when they did, were not good at judging the amount required – this should be unsurprising. It has made this history less state centered (Katz and Sachsse, 1996; Thane, 2000). This trend has been reinforced by a change of social policy in several countries in the 1980s, Britain and the United States in particular. The replacement of direct state provision of services by contractual relationships with charities and profit-making providers has given prominence to the concept of the 'mixed economy of welfare.'

Third, at a time when the clients of the welfare state are drawn from all citizens, contemporary studies of social policies have come to pay attention to the mixture of resources at the disposal of citizens, particularly of the elderly, whether these were from public, occupational, or commercial sources. Since that mixture differs in different countries, comparative studies have moved from an exclusive preoccupation with state provision toward a concept of welfare regimes more broadly defined (Esping-Andersen, 1990). The influence of comparative studies by social scientists on historiography is the final issue to be considered.

Comparative Studies

The historical study of welfare states was for a long time overparticularized. Attempts to identify categories suited for generalizations were left to social scientists specializing in the quantitative analysis of policy outcomes. This has been a dynamic field of study since the 1970s, but it developed in a particularly ahistorical form. One reason was its dependence on information provided by such international agencies as the United Nations and the Organization for Economic Co-operation and Development. Little of this went further back than the 1960s, so that the historical perspective was limited. Second, the questions asked and the explanatory power of the answers provided were constrained by the availability of such quantitative evidence, which was at first largely limited to figures of expenditure. The narrowness of these comparative studies was only slowly overcome as new evidence became available, e.g., the Luxembourg Income Study in the 1980s, which provided internationally comparable income-distribution data at microlevel, and as researchers began to approach national governments and other agencies directly to construct their own database. Third, the choice of appropriate categories for comparison across different national contexts is notoriously difficult and not always successful.

Evidence of this kind was, in any case, unable to provide explanations that advanced beyond the discovery of correlations. Intentions were ignored, because unsuited to standardization, and important dimensions of history were thereby ruled out of court. The most important result of these correlations was to group welfare state regimes into three main types: liberal, corporatist, and social democratic. It is more obvious that these describe ideal types than that they describe clearly differentiated clusters of indicators. Australians have demurred at the inclusion of their country in the same category as the United States; Germans have felt unhappy at being grouped with Italy and France; and the case of Britain is recognized widely as a hybrid. It is certainly not possible to write anything like a common history of the several welfare states grouped into any one of these types, with the possible exception of the four social democratic ones, who all happen to be Scandinavian.

Yet, by their very limitations, comparative empirical studies have helped to identify so-called anomalies and to encourage the intensive historical investigations of individual cases (Castles, 1989, which includes Japan and Israel). The gulf between the social scientific and the historical study of welfare states has narrowed, as indicated by sharply focused comparative histories of pensions and of public health or by a five-volume history of individual welfare states addressing similar questions and written on a common editorial plan (Baldwin 1990, 1999; Flora, 1986/2000).

Abstract

Work-related well-being encompasses burnout and its opposite, work engagement. Burnout is chronic psychological strain and somatic difficulties, consisting of the syndromes of emotional exhaustion, depersonalization (cynicism), and low-personal accomplishment (self-efficacy). Three theoretical models that explain well-being and burnout are conservation of resources, job demands-resources and person-job fit. The predictors of well-being and burnout include factors in the work environment and dispositional traits. The outcomes include work-related attitudes, performance, and dysfunctional behaviors. Intervention programs can be either person- or organization-directed, and should concentrate on not just reducing burnout but increasing engagement.

Well-being is living in a state that is, in some sense, good (Warr, 2013). Affective well-being concerns one's feelings, whereas syndrome well-being concerns perceptions, recollections, comparisons, and anticipations, as well as affective response. The state of one's well-being ranges from minimal or temporary changes to long-term degradation of mental and physical health. Work-related well-being is a specific aspect of subjective well-being, comprised of both positive and negative features. Most of the research on workers has focused on their long-term mental health state rather than on momentary fluctuations in mood and affect (Warr, 2013).

Conceptualizations of Well-Being and Burnout

Well-being comprises of two dimensions: displeasure-to-pleasure, and low- and high-mental arousal (Warr, 2013). Intersecting these dimensions yields four distinct states: (1) displeasure-low activation (e.g., cynicism), (2) displeasure-high activation (e.g., anxiety), (3) pleasure-low activation (e.g., job satisfaction), and (4) pleasure-high activation (e.g., job involvement).

Burnout is on the displeasure end that triggers low to moderate arousal levels. It is characterized by chronic psychological strain and somatic difficulties. Occupations that require frequent and intense interpersonal contacts with service recipients are especially at risk for burnout. For them, the relevant syndromes of burnout are *emotional exhaustion*, *depersonalization*, and *lack of personal accomplishment* (Maslach et al., 1996). Emotional exhaustion is the experience of mental fatigue from frequent and intense interpersonal contacts at work. Depersonalization is an unhealthy detachment from others. Lack of personal accomplishment is negative self-concept on the job. Recent evidence suggests that workers in nonservice industries also are at risk for burnout. For them, the relevant syndromes of burnout are *emotional exhaustion*, *cynicism*, and *lack of personal efficacy*. Cynicism is the formation of negative attitudes toward career and work. Lack of efficacy is reduced sense of mastery and effectiveness due primarily to external factors and beyond the individual's control.

As the mirror-opposite of burnout, work engagement is on the pleasure end that triggers moderate to high arousal levels (Warr, 2013). It is characterized by the persistent, positive affective-motivational state of fulfillment (Schaufeli and Enzmann, 1998; Maslach et al., 2001). The three syndromes of engagement are *vigor* (i.e., high energy and resilience), *dedication* (i.e., strong job involvement), and *absorption* (i.e., immersion in one's career/profession), which are relevant for workers across both service and nonservice industries.

Theoretical Models of Work-Related Well-Being and Burnout

The phenomena of work-related well-being and burnout can be understood through Hobfoll and Freedy's (1993) conservation of resources (COR) model. It states that workers strive to acquire, retain, protect, and foster valued resources and minimize any threats of resource loss. Threats to resource loss are usually in the form of role demands along with the energy and efforts expended toward meeting such demands. Workers invest their resources in meeting certain job demands with the expectation of receiving positive outcomes (i.e., rewards) in return and attempt to conserve their resources by making judgments about the resources that would be most helpful at any given moment. Well-being is diminished when valued resources cannot be regained.

Along similar lines, the job demands-resources model states that burnout stems from two parallel processes: (1) the effort required to meet demands; and (2) the resources that facilitate goal attainment (Bakker and Demerouti, 2007). Demerouti et al. (2000) discovered that energy depletion is driven by high demands and leads to emotional exhaustion, whereas the erosion of motivation is driven by a lack of resources and leads to depersonalization. Schaufeli and Bakker (2004) showed that adequate resources increase engagement, whereas both demands and inadequate resources increase burnout.

One's relational transactions in the workplace determine whether burnout or engagement will develop. Maslach and Leiter's (1997) person-job fit model states that incongruity between the worker and the job demands undermines well-being. Person-job mismatches can occur in six distinct areas: (1) workload, typically represented by having too many tasks without sufficient time to complete them, but also by

inadequate job-related skills; (2) control, especially in terms of lacking the resources necessary to do the job; (3) rewards, the existence of both extrinsic and intrinsic motivators; (4) fairness, which concerns mutual respect and confirms individuals' self-worth; (5) community, which provides members with a positive sense of connection to others at work and in society; and (6) values, especially in cases where job requirements are in conflict with one's personal values, or when one is caught between conflicting values within the organization or with society. The number of mismatches will have a cumulative adverse impact on well-being.

Predictors of Well-Being and Burnout

The work-related variables most widely linked to well-being and burnout is the demands of workload, role conflict and role ambiguity, and the resources of control, autonomy (Alarcon, 2011), and social support (Halbesleben, 2006). Alarcon (2011) found the demands to have the strongest relation with emotional exhaustion, supporting the COR model prediction that emotional exhaustion is a form of strain that occurs before the other burnout syndromes. Leiter et al. (2009) found that work overload contributed to exhaustion and cynicism; and more broadly, incongruity in values between the physician and the health care system contributed to exhaustion, cynicism, and low professional efficacy. The impact of value incongruity was stronger for women than for men. In contrast to demands, resources had a strongest relation with reduced personal accomplishment (Alarcon, 2011).

Occupations that involve frequent and intense communications with recipients often entail using emotional labor (Larson and Yao, 2005). As a job requirement, emotional labor becomes a demand (Wallace and Lemaire, 2007), but as means to facilitate job performance, it becomes a resource (Lee et al., 2010). Lee et al. found that among physicians, the hiding of emotions was associated with emotional exhaustion and physical symptoms of strain, suggesting that this was a strategy to reduce interpersonal demands. In contrast, the expression of a variety of emotions was associated with reduced depersonalization and physical symptoms of strain, which would encourage positive patient responses (Larson and Yao, 2005).

Beyond the interpersonal demands specific to the job, the broader context of the social work environment impacts well-being and burnout. Counterproductive work relationships can be expressed through incivility and displaced aggression/bullying. Workplace aggression/bullying has been linked to burnout (Lee and Brotheridge, 2006a) and diminished mental and physical health among those targeted and who witnessed such acts (Lovell and Lee, 2011).

Balancing between work and nonwork demands and resources are particularly challenging in many occupations. Among police officers, excessive workload taxes the resources needed to cope with the demands of law enforcement. This imbalance also has spillover effects on their nonwork roles, which often impact relationships outside of work (Lee and Brotheridge, 2006b). Physicians who experienced work–life conflict experienced emotional exhaustion (Lee et al., 2010), whereas physicians, who found time for interests outside of medicine, their family, and to maintain a healthy and active lifestyle, were able to achieve well-being (Wallace and Lemaire, 2007). Nonwork sources of social support are critical resources for achieving work–life balance, and thereby enhancing well-being and reducing burnout (Halbesleben, 2006).

In addition to work-related variables, dispositional traits have been linked to well-being and burnout (Alarcon et al., 2009). Alarcon et al. found the Big Five Model traits, positive and negative affectivity, self-esteem, self-efficacy, locus of control, optimism, proactive personality, and hardiness were all associated with burnout. Work-related variables and dispositional traits directly, as well as interact with each other, to impact well-being and burnout. For example, Hsieh and Wang (2012) found that the effect of job stress on burnout was moderated by locus of control, where the relationship was weaker for internals than for externals in accounting auditors.

Outcomes of Well-Being and Burnout

Work-related attitudes have been linked to well-being across many occupations (Alarcon, 2011). Consistent with the COR model, the burnout dimension of emotional exhaustion was most strongly associated with job dissatisfaction and reduced organizational commitment, and a moderate relation with turnover intentions. Turnover intentions have also been linked to burnout (Leiter and Maslach, 2009). Leiter and Maslach found that work–life incongruence was associated with the burnout syndrome of cynicism, which in turn, was associated with turnover intentions in nurses. Both burnout and engagement impact job performance and outcomes tied to performance (Maslach et al., 2001). Bakker et al. (2004) found that emotional exhaustion was negatively associated with peer-ratings of in-role performance (e.g., 'Achieves the objectives of the job'), whereas engagement was associated with extrarole performance (e.g., Takes initiative to orient new employees to the department even though not part of his/her job description). Taris (2006) found that emotional exhaustion was strongly negatively associated with customer satisfaction. Burnout also can adversely impact patient safety (Halbesleben et al., 2008). Halbesleben et al. found that burnout was negatively associated with reporting of mistakes that did not lead to adverse events.

Burnout has been linked to substance abuse and various dysfunctional behaviors outside of work (Johnson et al., 2005). Johnson et al. found that in police officers, burnout was associated with alcohol abuse, rigidly applying standards of work to the home, and the frequency of violent behaviors directed toward their spouse. Other researches have found strong ties between burnout and the deterioration of family and social relationships, with adverse spillover and contagion effects on the worker's spouse/partner and family members (Lee and Brotheridge, 2006b).

Intervention Programs

Burnout intervention programs are person-directed, organization-directed, or a combination of the two (Korunka et al., 2013). Person-directed interventions include psychotherapy, counseling, exercises for relaxation, and adaptive skills training.

Communication skills training in the service professions not only reduce burnout but can heighten engagement. Such training includes both verbal and nonverbal communications and the ability to express empathetic concern to recipients (Larson and Yao, 2005). For example, method-acting exercises may help trainees in the health care industry vicariously experience their patients' feelings and motives and facilitate appropriate responses. Ramirez et al. (1995) believe that communication skills training will not only reduce the risk of burnout, but contribute to physicians' satisfaction with their practice, which, in turn, positively influences patient outcomes.

Organization-directed interventions include changes in the work procedures, task restructuring, modifying job demands, increasing job control or the level of participation in decision-making, clarification of role expectations, performance-based incentives, developing a respectful work climate, and cultivating interpersonal relations with colleagues and clients. Research suggests that combined person and organization-directed interventions will lead to significant reductions in burnout, especially emotional exhaustion (Awa et al., 2010). Programs that address the motivational and resource needs of those most at risk for burnout will have the best chance for success. However, they require periodic follow-up interventions to prevent the recurrence of the conditions that led to burnout in the first place (Awa et al., 2010).

Maslach et al. (2001) recommend that intervention programs should concentrate on ways to increase engagement rather than merely seek to reduce burnout because engagement is more closely aligned with the idea of embracing and drawing on the potential of the human spirit to improve the quality of work–life. From this perspective, promoting congruity between individuals and their work entails providing resources that do more than fill existing gaps or offer monetary or material support (i.e., extrinsic motivators). Instead, organizations should present resources that foster intrinsic motivation, and thereby create heightened career involvement, enthusiasm, and significance.

Wellbeing and Burnout in the Workplace: Organizational Causes and Consequences

Sabine Sonnentag, University of Mannheim, Mannheim, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Well-being is a multidimensional concept, with burnout being a specific job-related construct of poor well-being. This article provides definitions of well-being and burnout, and introduces the new concept of work engagement. It briefly presents theoretical models on job-related well-being and burnout. It summarizes empirical studies on workplace and personal factors contributing to job-related well-being and burnout as well as studies on job-related consequences of poor well-being and burnout. Interventions for improving job-related well-being are also described.

Conceptualizations of Well-Being and Burnout

Job-related well-being is a specific aspect of subjective well-being and comprises positive features such as work engagement, job satisfaction, job attachment, job involvement, and job morale; impaired job-related well-being includes experiences such as job tension, depression, burnout, and alienation from work. The well-being concept refers to both minimal and temporary changes in employee mood and more long-term disturbances in mental health (e.g., chronic anxiety or psychosomatic complaints). It is typical for work-related research to examine mental health and well-being in normally working samples who are not psychiatric patients.

Job-related well-being is a multidimensional concept. Based on the conceptualization of arousal and pleasure as two independent dimensions, Warr (1987) proposed a model of job-related well-being comprising three dimensions: the first dimension runs from displeasure to pleasure, the second from anxiety to comfort, and the third from depression to enthusiasm. Additionally, feelings of competence and aspiration can also be regarded as facets of job-related well-being.

Burnout is a specific and severe form of disturbed job-related well-being, originally mainly observed in human service professionals. According to Maslach and Jackson (1981), the burnout syndrome comprises emotional exhaustion, depersonalization (i.e., negative and cynical attitudes toward one's clients or patients), and reduced personal accomplishment as the key dimensions. More recently, Demerouti et al. (2001) have conceptualized exhaustion and disengagement as the two main components of burnout. During the past decades, researchers have observed that burnout not only develops in human service professions but can also occur in all kinds of jobs.

While most research examined negative aspects of well-being, Schaufeli and Bakker (2004) proposed to focus on work engagement as a positive aspect of job-related well-being. Work engagement comprises three dimensions: vigor, dedication, and absorption. It is a positive state of mind that becomes evident in the process of working. Whereas negative aspects of well-being such as burnout seem to be more influenced by job stressors, work engagement tends to benefit from job resources (e.g., job control).

Theoretical Models on Job-Related Well-Being and Burnout

During the past 50 years, researchers have put much effort into the development of theoretical models on the relationship between work situation factors and job-related well-being and burnout. Among the most prominent models are the job characteristics model (Hackman and Oldham, 1976); person–environment fit theory (Harrison, 1978); the job demand–job control model (Karasek and Theorell, 1990), along with its refinements (e.g., Demerouti et al., 2001); the vitamin model (Warr, 1994); and the effort–reward imbalance model (Siegrist, 1996).

In their job characteristics model, Hackman and Oldham (1976) specified five core job characteristics that are assumed to be crucial for high internal work motivation and employee satisfaction: skill variety, task identity, task significance, autonomy, and feedback from the job. These job characteristics are expected to impact critical psychological states (i.e., experienced meaningfulness of the work, experienced responsibilities for work outcomes, and knowledge of the results of work activities), which in turn impact the motivation and satisfaction as outcome variables. Furthermore, Hackman and Oldham proposed that moderators such as growth need strength, contextual satisfaction, knowledge, skills, and abilities have an effect on the relationship between core job characteristics and critical psychological states and also on the relationship between critical psychological states and outcome variables. Humphrey et al. (2007) provided a comprehensive overview over the empirical research on the job characteristics model.

Person–environment (P-E) fit theory (Harrison, 1978) proposes that strain occurs when characteristics of the job environment do not fit the individual. Two types of fit between an individual and the environment can be differentiated: the fit between the demands of the environment and the abilities and competencies of the person (demands–abilities fit), and the fit

between the needs of the person and supplies from the environment (needs–supplies fit). According to P-E fit theory, well-being suffers when environmental demands exceed the person's abilities and when the person's needs exceed the supplies provided by the environment. Meta-analytical evidence shows that demands–abilities fit and needs–supply fit are indeed positively related to well-being indicators (Kristof-Brown et al., 2005).

The job demand–job control model (Karasek and Theorell, 1990) received much attention within work and organizational psychology. In its original version, the job demand–job control model describes two dimensions relevant for job-related well-being: job demands and job control. In this model, job demands refer to high workload and time pressure, and job control includes decision authority and intellectual discretion. The model proposed that the combination of high job demands and low job control becomes evident in so-called high-strain jobs that have severe negative effects on employee well-being. The original model further assumed that a combination of high job demands and high job control results in active jobs that have more effects on employee well-being. Later, other work situation factors, such as social support and informational control, have been incorporated into the job demands–job control model (Karasek and Theorell, 1990).

Demerouti et al. (2001) extended the job demand–job control model into a more general job demands–job resources model. Importantly, Demerouti et al. suggested that in addition to job control, other resources (e.g., feedback, reward, participation, supervisor support) can also buffer the negative effects of job demands on poor well-being or burnout. In addition, this model stated that job resources in itself have motivational power and increase work engagement (Schaufeli and Bakker, 2004).

In his vitamin model, Warr (1994) proposed that job-related well-being is affected by job characteristics in a way similar to the effects of vitamins on physical health. Basically, the vitamin model suggests that some job characteristics have a linear effect, whereas others have a nonlinear effect on well-being. Among the job characteristics assumed to be linearly related to well-being are physical security, a valued social position, and availability of money. Job characteristics assumed to show a curvilinear relationship with well-being include opportunity for personal control, opportunity for skill use, externally generated goals (i.e., demands), variety, environmental clarity, and opportunity for interpersonal contact. More specifically, the vitamin model assumes that well-being increases as these latter job characteristics increase; however, at a very high level, these job characteristics will cause a decrement in well-being.

The effort–reward imbalance model (Siegrist, 1996) builds on the assumption that the effort a person invests in his or her job and the rewards he or she gets are crucial for the person's well-being and health. Effort may result from extrinsic (e.g., obligations and demands of the job) and intrinsic (e.g., resulting from a high need for control or approval) demands. With respect to rewards, money, esteem, and status control (e.g., job stability, career advancement) can be differentiated. In essence, the model proposes that a lack of reciprocity between effort and rewards is experienced as stressful and leads to impairments in health and well-being. Empirical studies tend to support this view (Van Veghel et al., 2005).

Predictors of Job-Related Well-Being and Burnout

Empirical research has identified job stressors and job resources as the core predictors of job-related well-being and burnout. In addition, personality variables can also explain interindividual differences in job-related well-being and burnout. With respect to job stressors (i.e., events and conditions in the work situation that evoke strain reactions), there is evidence that employees who face a high workload and time pressure report a poorer job-related well-being (De Lange et al., 2003) and higher levels of burnout (Crawford et al., 2010). Moreover, so-called hindrance stressors (e.g., hassles, interruptions, situational constraints, organizational politics) are related to poor job-related well-being and burnout (Crawford et al., 2010), with hindrance stressors often showing larger effect sizes than workload or time pressure. Probably, job conditions that make it difficult and effortful for employees to accomplish their tasks are more detrimental than the sheer amount of work. Research further showed that work-related critical incidents (i.e., unexpected and severe events such as the death of a patient a health professional is caring for) predict symptoms of anxiety and depression (de Boer et al., 2011). Moreover, workplace bullying is related to mental health problems such as anxiety and depression as well as burnout (Nielsen and Einarsen, 2012).

Overall, longitudinal studies support the view that the effect of job stressors on poor well-being and burnout is stronger than the effect of poor well-being or burnout on the exposure and perception of job stressors (Sonnentag and Frese, 2012). This pattern of findings speaks for a stronger causal effect from stressors on strains than from strains on stressors. However, with respect to workplace bullying, it turned out that this stressor predicted mental health problems to a degree similar in size as to which mental health problems predicted workplace bullying (Nielsen and Einarsen, 2012). Thus, the experience of workplace bullying might contribute to a vicious cycle, with vulnerable employees suffering most from this type of job stressor.

When it comes to the predictors of work engagement, it is important to differentiate between two types of job stressors. Challenge stressors such as a high workload are positively related to work engagement, whereas hindrance stressors (e.g., situational constraints, hassles, social conflicts) are negatively related to work engagement (Crawford et al., 2010). Combining these findings with the findings on the predictors of poor well-being and burnout, challenge stressors reveal an ambivalent nature: they are related to high work engagement *and* to strain symptoms and burnout. Possibly, they are energizing and – at least under some circumstances – depleting at the same time.

Job resources are conditions at work that help perform well or deal with stressors in a positive way. Job control (i.e., autonomy) and social support belong to the most frequently studied job resources. Studies have shown that job control is positively related to well-being (De Lange et al., 2003; Humphrey et al., 2007) and low burnout levels (Crawford et al., 2010). When employees have some discretion about how to do their job, they experience a better well-being and are less exhausted. Also, social support was found to be a positive factor in the workplace, showing negative

correlations with burnout (Halbesleben, 2006). Employees who receive a high level of social support from their supervisors and coworkers enjoy a better well-being than persons who lack social support. Similarly, job resources are also positively related to work engagement (Christian et al., 2011; Crawford et al., 2010). In addition, leadership variables predict work engagement (Christian et al., 2011).

It has been argued that job resources, particularly job control, buffer the negative effects of job stressors on well-being (e.g., Karasek and Theorell, 1990). Empirical evidence for this buffer hypothesis, however, is mixed (De Lange et al., 2003). It has been suggested that the resources must match the stressors that they should buffer, otherwise they are only of little help (Daniels and de Jonge, 2010).

Job-related well-being and burnout depend not only on employees' job stressors and job resources but also partly on their personality. Alarcon et al. (2009) identified negative affectivity (i.e., low levels of emotional stability) as a strong predictor of burnout. It might be that employees with high levels of negative affectivity see their work environment in a more negative light and are less able to cope with job stressors. In addition, other individual difference variables such as low general self-esteem, low general self-efficacy, and an external locus of control are related to elevated burnout levels (Alarcon et al., 2009). Also, work engagement seems to depend on personality factors. Particularly, conscientiousness, positive effect, and proactive personality are substantially related to work engagement (Christian et al., 2011).

Person-related factors have also been examined as moderators of the relationship between job stressors and poor well-being or burnout. For instance, emotional stability was found to buffer the negative effects of job stressors (Kammeyer-Mueller et al., 2009). Recent research has demonstrated that also processes happening off the job play a role for job-related well-being and burnout. For instance, when employees mentally detach from work during their leisure time (i.e., temporally disengage from the demands of their jobs), they enjoy a better well-being, particularly when job stressors are high (Sonnentag, 2012).

Taken together, job-related well-being and burnout have multiple causes that lie partially in employees' work situation, partially in their personality and their life off the job. It seems that particularly the combination and interplay of various factors are responsible for a person's job-related well-being.

Consequences of Job-Related Well-Being and Burnout

Low job-related well-being and burnout are not only unpleasant experiences but they may also threaten the individual's functioning within the work organization. Research shows that poor job-related well-being is negatively associated with task and contextual performance (Ford et al., 2011). This negative relationship between poor well-being and performance was found for various performance measures (self-reports, supervisor and peer ratings, organizational records), suggesting that the empirical correlations cannot be reduced to a pure perceptional bias. Interestingly, the effect sizes tend to be higher for these more psychological well-being indicators than for physical symptoms (Ford et al., 2011). When looking specifically at burnout, research demonstrates significant correlations between burnout and objective performance indicators as well as customer satisfaction (Taris, 2006). Moreover, burnout also matters for safety issues: employees with elevated burnout levels experience more adverse events, accidents, and injuries (Nahrgang et al., 2011). In contrast to burnout and other impairments of job-related well-being, work engagement was found to be positively related to task and contextual job performance (Christian et al., 2011).

When interpreting these findings, one has to take into account that most studies used cross-sectional designs. Thus, the results do not necessarily imply that poor well-being and burnout have a causal effect on performance. It might be that performance has an effect on job-related well-being or that both well-being and performance are influenced by other factors such a leadership behavior or organizational climate.

Intervention Programs

Different kinds of interventions aim at the protection and improvement of job-related well-being. Most interventions are oriented toward the individual, i.e., to the way an individual perceives or deals with unfavorable work situations. Other individual-oriented interventions are designed to directly influence the individual's psychological and physical well-being, for example, by progressive muscle relaxation, cognitivebehavioral interventions, or meditation techniques. Empirical evaluations of these programs provide evidence for the effectiveness of interventions based on the behavioral–cognitive approach as well as on relaxation or meditation (Richardson and Rothstein, 2008), with behavioral–cognitive interventions showing the largest effect sizes. Interestingly, multi-method approaches (i.e., interventions that combined methods and exercises from a variety of conceptual frameworks) resulted in smaller – albeit still significant – effect sizes (Richardson and Rothstein, 2008), perhaps because they are less successful in giving employees a clear focus and guidance about what to do in a stressful situation. In addition to these specific stress management approaches, interventions that aim at lifestyle changes and that increase efficacy beliefs are also successful in improving well-being (e.g., Chen et al., 2009). For instance, workplace interventions that stimulate increased physical activity are associated with better well-being (Conn et al., 2009).

Another approach to improve job-related well-being focuses on workplace interventions. During such workplace interventions, jobs are redesigned, for instance, by increasing employee job control, by reducing job stressors, or by increasing job resources. Empirical studies show beneficial effects of such workplace interventions on job-related well-being (e.g., Holman et al., 2010). Overall, the effect sizes of all intervention programs vary largely in size, suggesting that they have to be tailored to the specific requirements of the situation and to employees' needs.

Western and Non-Western Views of the Social and Behavioral Sciences: De-Westernizing the Social and Behavioral Sciences

Thomas Brisson, University Paris 8, Saint-Denis, France

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The expression de-Westernization of the Human and Behavioral Sciences refers to two different trends. First, it designates their diffusion outside their Western context of origins, through the establishment of national universities and disciplines, the migrations of scholars, the internationalization of scientific organizations, etc. In the second sense, it stands for the attempts to create Human and Behavioral Sciences not predicated on Western epistemological frameworks. Theses two trends have developed since the nineteenth century and have led to a wide range of situations, with the assimilation of the Western scientific apparatus being linked to their more or less partial rejection.

The expression de-Westernization of the Human and Behavioral Sciences refers to two different trends. In the first sense, it designates their diffusion outside their Western context of origins. This diffusion has consisted in various processes, such as the establishment of disciplines nationally, as well as the material and institutional background that made this creation possible (the establishment of national universities, the migrations of scholars, the internationalization of scientific organizations, etc.). In the second sense, the concept of de-Westernization stands for the attempts to create Human and Behavioral Sciences not predicated on Western epistemological frameworks (see, for instance, Alatas (2006) calls to frame an Asian sociology independently of the 'European Founding Fathers,' Durkheim, Marx, and Weber).

De-Westernization as the global diffusion of Human Science and de-Westernization as a theoretical program have both developed from the nineteenth century on, but have interacted in various ways. They sometimes occurred simultaneously, with the internationalization of human sciences leading to a criticism of their Western apparatus. But the reverse was equally true when the indigenization of European theories did not give rise to any epistemic challenge. Most of the time, a combination of these two trends prevailed. The first encounter with Western theories, under colonial pressure, prompted both their creative appropriation and the denunciation of their imperialistic origins. The same ambivalence continued shaping the approaches of the newly decolonized societies, where the Western scientific apparatus was implemented to build modern societies and denounced in the name of national independence. In this respect, the current situation is in line with process: in a context where Western supremacy is contested, attempts to 'provincialize' European theories are nevertheless struggling with their unprecedented diffusion and political importance (Chakrabarty, 2000).

This conflicting process must therefore be analyzed with reference to its multiple situations. De-Westernization had as many illustrations as there were different national paths, historical situations, and scientific disciplines. Such a diversity of situations notwithstanding, it is possible to gain a better understanding of scientific de-Westernization by focusing on its most salient aspects. De-Westernization took place, first, in a context shaped by the colonial encounter and the disruption of the existing intellectual traditions. The implementation of the Western scientific apparatus outside the boundaries of Europe was then prompted by the efforts to build institutions and to train scientific professionals: the migrations of scholars to the West, or the creation of universities and research centers, are among the most significant achievements of this policy. On a third level, de-Westernization was closely linked to the international and transnational scientific organizations that were set up during the last two centuries.

These three points aim at better characterizing the sociological and historical processes that led to the disputed indigenization of Western sciences. By contrast, two last points scrutinize what functions human sciences fulfilled in non-Western societies. They show how human sciences were instrumental in defining political concepts that acted as rallying cries against perceived forms of scientific and cultural hegemony. In line with this political approach, they finally focus on the idea of 'de-Westernization as a scientific program' and analyze what were their argumentative strategies.

An analysis of the de-Westernization of the human and behavioral sciences would imply tackling all the disciplines in every non-Western country. Needless to say that it was not possible to cover such a variety of situations. The cases of anthropology, psychology, and sociology will receive more attention. Accordingly, China, India, Japan, and specific parts of the Muslim world will be more precisely dealt with. Finally, central historical periods and scientific turning points were given priority, over the homogeneous course of 'normal science.'

(Pre)Colonial Encounters

Western human sciences are now everywhere: officials of African states and NGOs use the same statistics than their North American colleagues. Mental suffering is categorized, in India or in Algeria, according to a conception of the self elaborated by modern European psychology. As for Chinese or Japanese anthropologists, who study the ethnic *Miao* or *Ainu* the way English or German anthropologists mapped the world tribes. If human sciences originally stem from the revolutions that have reshaped Europe at the modern times, they have now spread well beyond the European boundaries.

These changes were linked to the diffusion of European modernity on a global scale and the universal acceptance of Western political ideas, cultural forms, and bodily practices. Yet the acculturation of human sciences followed specific channels. To gain a better understanding of this process, it is useful to differentiate between the diffusion of human sciences in terms of 'content' and 'form.' With regard to their *content*, the acclimation of human sciences implied that Western theories spread outside Europe: for each discipline, canonical authors and their main concepts were translated. Some became extremely influential (see Charles Darwin (1809–82) in the Arab world (Elshakry, 2014) or Herbert Spencer (1820–1903) in China). The European authors who had written on non-Western questions equally received a great deal of attention, as local scholars were interested in the way Western scientists had understood their societies. Joseph Needham's *Science and Civilization in China* practically redefined the understanding the Chinese had of their sciences. Others had a less-enthusiastic reception, such as Renan, whose views on Islam prompted a critical response from Al-Afghani, or Weber's analysis of Buddhism or Confucianism in Asia.

These authors were certainly challenging for non-Western scholars, but to a certain extent only. For people who had rich intellectual traditions, it was possible to dismiss Marx or Comte, or to hold them in low esteem compared to Ibn Khaldun or Confucius. Many local scholars also stressed the numerous parallels between Western and canonical non-Western authors. The content of European human sciences was then easy to appropriate. Such was not the case, yet, with the *form* of human sciences. As 'circulating forms,' they had a 'performativity' (Appadurai, 2013) that completely redefined native intellectual traditions. Human sciences were premised on patterns, sets of relations, and scales of analysis that soon made it impossible to continue using local schemes. Besides, the cogency of European human sciences and their internal coherence made them powerful intellectual tools. For all these reasons, they came to quickly supersede other scientific systems. China is a case in point, where a two-millennia-old system of thinking based on the idea of correlation was replaced, in less than a few decades, by European sciences and their concept of causality (Vandermeersch, 2013).

Moreover, the global acculturation of human sciences had dramatic consequences as it was linked to imperial expansion and came to play a key role in the strengthening of the European rule (Said, 1978). Yet this early process of diffusion was equally fraught with indeterminacy and ambivalence. In the course of the colonial penetration, many local scholars came to collaborate with their European peers. They became familiar with a set of knowledge that cannot be reduced to its imperialistic purposes and they gained a new understanding of their societies (Pouillon and Vatin, 2011). A product of European modernity, human sciences became tools that local scholars could use to make sense of the transformations this very modernity had imposed on them.

Yet not all countries had the same resources to adapt to the changes. Many African or Asian societies, who had resisted state-based organizations, strove to keep the European influence remote. But they were unable, until the recent decades, to set up policies to catch up with the new scientific challenges. Others, on the contrary, had firmly established states and centuries- sometimes millennia-old scholarly traditions. They could therefore more easily react to the new situation.

It was the case in the Ottoman Empire, where the central power in Istanbul had been monitoring the European scientific progress since the eighteenth century. Its administrative structure and the ancient tradition of Muslim scholarship allowed setting up a coordinated policy of intellectual exchanges. It was also the case in Egypt, where a nascent nationalism led Muhammad Ali to open up to the West in the middle of the nineteenth century, in order to strengthen his autonomy toward the Caliphate. Among all the attempts made at this time, yet, Japan stand as the most successful. Despite its 'closed-country policy' that had severed ties with the outside, Japan had been watching the development of Western knowledge and technics, mainly through backdoor contacts with Dutch merchants. Besides, the country had its own tradition of scholarly investigation, which allowed for a swift importation of human sciences: the numerous essays on the particularities of the Japanese language paved the way for modern linguistic, and the administrative accounts of the population for the acclimation of demographic and sociological sciences. In a few decades, Meiji's Japan managed to successfully graft Western human sciences to her German-inspired academic structure. Here again, this was possible only because the former *Shogun* had established a centralized state, which proved decisive when Emperor Meiji (1852–1912) launched the Westernization of the country.

Despite the diversity of reactions, these countries faced more or less the same situation. They had to cope with the disruption of the native cultures brought by the European epistemological systems. There remained classical *Adib* or Confucian scholars in the Arab world or in China, after the West had swept in their countries, but what they could write would never have the same weight. Significantly, they came to be referred through exonymes. The *Ru Jia* became *Confucians*, a label that had been absent from the Chinese culture until the European unified a disparate body of texts under the name of Confucius. *Falsafa*, accordingly, was now referred as *Muslim* or *Arabic Philosophy*, whereas the discipline had always stressed its Mediterranean legacy. In this respect, the introduction of Western knowledge did not put an end to other culture's episteme. Rather it disrupted their unquestioned centrality and made them 'local' or 'alternative.'

Consequently, all countries saw a growing split between 'modern' and 'traditional' scholars. The formers were taught in the West or Westernized schools, and were expected to contribute to the modernization of their countries. The latter, provided they had retained some sort of authority, tried to keep the existing intellectual traditions alive. Yet the divide was not always a clear-cut one until the last part of the nineteenth century. In the Muslim world, the scholars who introduced Western theories had been raised in traditional schools and saw no contradiction between their education and the Western scientific apparatus. As they were supposed to be universal and appropriable by non-Western people, the Ottomans thought it appropriate to reformulate Western theories in the Koranic idiom (Aydin, 2007). Reformist thinkers like Jamal-Eddine Al-Afghani (1838–97) or Muhammad Abduh (1849–1905), accordingly, had no dilemma when they had to combine their training in Muslim exegesis with the new knowledge they

encountered in Europe. It is only with their follower Rachid Rida (1865–1935), at the end of the nineteenth century, that the difference between European and Muslim knowledge came to be seen as unbridgeable. At first a fierce supporter of intellectual modernization, Rida made a radical turn toward traditional scholarship and faith. Westernized intellectuals, at the same time, began to feel alienated from their native culture and promoted projects of Westernization that were more and more incompatible with the ancient intellectual systems.

As the aforementioned examples show, the capacity to oppose Westernization was to a large extent linked to the existence of a strong political apparatus and ancient traditions of knowledge. These very resources could nevertheless have opposite effects, when existing concepts led to misunderstandings and mistranslations. In Japan, when they introduced sociology, scholars had to struggle to frame a concept that adequately conveyed the new meaning of 'society.' They used ancient Chinese ideograms but were unsatisfied as they retained the idea of a loosely affiliated group of persons. It took them years to finally elaborate the concept of *Shakai* (see the article 'Translating Sociology into Japanese, Chinese and Korean Language'). Many countries were not as successful as Japan, though, and faced deep crisis. In China, the strong imperial state and the ancient scholarship paradoxically impeded the reception of European sciences. With its millennia-old scientific system, China could legitimately boast to be one of the major cultures in the world. But this self-confidence had already limited the contacts with the Jesuits at the sixteenth century. Three centuries later, many Chinese scholars and officials were equally blinded to the novelty of European knowledge. They assumed that it was in no way superior to their own and did not bother pondering over its threats.

The problem was not solely intellectual, but political. Several Chinese politicians and scholars from regional background had gained familiarity with European sciences, through contacts with missionaries or during stays in Japan. As they were fully aware of the new situation, they began acknowledging a full-fledged scientific modernization of China. Some local reforms were implemented at the end of the nineteenth century but were stopped by conservative cliques and literati classes in Beijing. The status quo prevailed and China faced a deepening crisis in a context of imperialism. The situation became so serious that imperial officials had to come with a compromise, known as the *Ti-Yong* principle. They differentiated between Chinese knowledge, supposed to shape the moral core and substance (*ti*) of the Chinese society, and Western knowledge, a set of purely functional means (*yong*) designed to modernize China. Yet the Chinese were to discover that Western knowledge and technics were not value-neutral and that it was impossible to acclimate them without affecting the society at large. The failure of the *Ti-Yong* principle worsened the crisis. In 1911 only, as the Empire collapsed, a new generation of politicians and scholars seized power and began modernizing China. They held Confucianism responsible for the precarious situation of China. Confucianism practically lost all its influence and was replaced by Western sciences (Levenson, 1968).

The *Ti-Yong* principle is similar to what almost all non-Western countries tried to implement. In the Ottoman Empire, scholars sought a balance between their Muslim legacy and the new European scientific systems. Some saw no contradiction; others, especially in times of imperialistic encroachments, came to limit the Western influence. The situation was easier for Japanese scholars as Japan had successfully contained the European expansion. Here too, nevertheless, Emperor Meiji promoted a revival of the Confucian values, to provide the society with moral landmarks. Western knowledge was everywhere; yet traditional systems survived, devoid of any epistemological value but with a strong ethical stance. The Japanese had managed to implement what the Chinese had envisioned. Japan had begun reconsidering her traditions already in the eighteenth century and her scholars had more leverage to 'reinvent' a flexible Japanese culture. Non-Western scholars came to Japan, sometimes from as far as Egypt, to understand how the country had achieved a balance between a sweeping scientific modernization and a strong sense of oneself. They later advocated various solutions that illustrate the diversity of the ways human sciences globalized beyond the European frontiers and reshaped non-Western societies.

The Institutional and Material Context of Scientific De-Westernization

Acclimating human sciences in countries where they were hitherto unknown implied implementing structures where these sciences could be developed and taught. Local governments built universities, research centers and created disciplines on the Western model. They also sent scholars and students abroad. Here again, the more autonomous the local rulers, the more leverage they had to set up this structure. In countries where the colonial rule was stronger, the same process occurred through different channels, with the Europeans opening universities that came to play a new role after the independence.

The setting up of (national) universities was the first step to introduce human sciences. Universities were created all over the world, following the European model, at the turn of the nineteenth and twentieth centuries. The University of Tokyo was established in 1877, Peking University in 1898, and Cairo University in 1908. Local rulers created universities in order to introduce Western knowledge and to strengthen their nations. They hired foreign staffs to teach new disciplines. Universities quickly superseded the old educational system. As modern official institutions, they had a prestige ancient schools did not have anymore. Besides, they trained large number of students, who, when they became officials or prominent intellectuals, contributed to legitimate and reproduce the new structure. These transformations affected classical institutions like the Islamic *madrasa* or the Chinese academia. Koranic schools did not cease to exist but were to focus almost exclusively on religious learning. In China, a sweeping change took place as the imperial examination system, which had been formally implemented at the beginning of the seventh century, was suppressed in 1905, a few years after the first modern university was created.

The countries where the colonial rule was more coercive experienced similar changes but at a different pace. The University of Algiers was established in 1909 by the French

colonizers, and the Universities of Calcutta and Bombay/Mumbai in 1857 by the English. The former nevertheless trained very few 'Muslim students' until the middle of the twentieth century: at the end of the 1950s more Algerians were studying at the Sorbonne in Paris than in Algiers. The University of Algiers was an institution committed to teach the Europeans and to exclude the Muslims. It is only after the independence in 1962 that the modern academic system became largely opened to the Algerian population, as it was supposed to contribute to the building of the nation.

In colonized as well as more autonomous countries, universities accommodated research departments where human sciences took roots. Psychology was lectured at the University of Tokyo in 1877 and became part of the curriculum in 1879. The first laboratory of psychology was established at the University of Calcutta in 1905 and at the National University of Peking in 1917. Sociology, accordingly, was institutionalized in the same decades, with Ernest Fenollosa teaching American-styled sociology at the University of Tokyo in 1878 and Masakazu Toyama becoming the first professor of sociology on 1893. In China, sociology had been lectured since 1905 on a rather irregular basis. A department of sociology opened in 1913 at Huijiang University, with mainly foreign academics, and in 1921, the first department with a completely Chinese staff was inaugurated at Xiamen University. In India, sociology developed, in the early decades of the twentieth century as the colonial authorities had to classify the population: a department was established in 1919 at the University of Bombay and several others followed elsewhere.

During the same decades, associations and journals began blooming. China provides an illustration of this global process, where a Fund Board of Chinese Education and Culture, with several social research institutes, was established in 1924. Accordingly, the *Chinese Society for Psychology* was created in 1921 and published a journal called *Xinli*. Chinese anthropologists also set up various societies in the 1920s; in 1930 they merged and became the *Chinese Society for Folklore Studies*, which published its own journal in the subsequent years (Blowers, 2006).

Most of the time, academic disciplines became national. Some attempts to create transnational or regional associations nevertheless took place at this time, for instance, in 1930 when the South-East Asian Association of Sociology replaced the Chinese Association of Sociology. But it is mainly after the Second World War that this trend gained momentum. Besides, the de-Westernization of human sciences that took place in the interwars did usually not lead to challenge their epistemological tenets. True, some Japanese scholars called for distinct Asian human sciences in the 1930s but, in a context of Japanese imperialism, the move was politically motivated. In fact, most of the local scholars involved in the creation of national disciplines during the first half of the twentieth century aimed at replicating European sciences as accurately as possible. Even though they could have a critical stance, they deemed more important to fully understand them and to provide their country with this central outcome of modernity.

As important as universities and associations, was the development of academic journeys and scientific pilgrimages. Local authorities, provided they had enough political leverage, sent students and scholars to the West in order to study the new disciplines. Muhammad Ali sent the first Egyptian mission to Paris in 1826. After 5 years in France, its chaplain, Rifa'a al-Tahtawi (1801–73), wrote the *Takhlis al-Ibriz fi-Talkhis Bariz* (translated as *A Paris Profile*), which became a landmark book in the Arab rediscovery of European culture. Tahtawi was then appointed head of a translation office that contributed to the acclimation of Western philosophy and human sciences. Egyptian students missions continued during the next century and allowed generations of scholars to gain familiarity with European epistemological systems, especially human sciences. Likewise, the Japanese government sent academic missions to Europe and the United States, following Emperor Meiji's declaration that his subjects 'should seek knowledge all over the world.' In 1871, officials and scholars took part in the two-year-long Iwakura Mission. Sixty students were brought along and some of them were left in various countries to complete their studies. When they came back to Japan they set up colleges and universities, translated essays and books; some became influential scholars. Accordingly, the first translators of human sciences in Japan were, directly or indirectly, influenced by the outcome of the mission. As such travels proved crucial to the intellectual modernization of the country, Japan issued more than 10 000 students passports until the end of the nineteenth century.

The Western powers also perceived academic exchanges as an important question of international politics. The United States used a large part of the money remitted by China after the Boxer War to sponsor students' scholarships to the US. Consequently, most of the first Chinese sociologists or psychologists had studied at Columbia or at the University of Chicago and, when they came back to China, they contributed to set up associations and academic departments. If the Chinese imperial authorities had only reluctantly let students go to the United States, the subsequent governments were much more willing to develop exchanges, as they were now supporting the modernization of China's universities (Ye, 2001).

Modern academic pilgrimages clearly show that, at the end of the nineteenth century, intellectual and scientific issue had become a major political concern and that the West was at the center of intellectual exchanges. Granted, nonofficial journeys still existed: when Jamal-Eddine Al-Afghani and Mohammad Abduh toured Europe in the 1880s, they did it without any state support. But this was becoming more and more the exception, as official grants and then the support of private foundations became the main source of mobility. Accordingly, not all journeys brought scholars and students to the West: many continued to go to non-Western countries. For instance, around 10 000 Chinese students went to study to Japan during the first decades of the twentieth century. This was crucial for the development of human sciences in China, for the Japanese had translated many notions that their Chinese peers borrowed. But the journey to Japan was not the goal in itself: the country was seen as the shortest way to European modernity and its most successful illustration.

International and Transnational Networks

To a large extent, the de-Westernization of the human sciences that took place at the nineteenth and the beginning of the

twentieth century was tantamount to a nationalization of European disciplines, in which local authorities played a key role. Yet de-Westernization was also a process in which international and transnational actors took a large part, sometimes even before the implementation of national disciplines. International scientific associations were instrumental in the creation of national associations of human sciences in non-Western countries. But they were not the only ones as nonstates actors were also involved: this is the case of churches on the one hand, and of movements such as Marxist or feminist networks, on the other.

As the previous example of academic journeys highlight, the de-Westernization of human sciences occurred through international contacts. National authorities tried to control the process, but they had to collaborate or to compete with international actors. The internationalization of the scientific life began at the nineteenth century, as an attempt to overcome the fragmentation of the academic community (Guilhot et al., 2008). The first international scientific associations were created before the twentieth centuries but they remained almost exclusively European until the 1950s. The only exception, here again, were the Japanese who took part in international associations from the nineteenth century on. In 1873, at the first International Conference for Oriental Studies, the Japanese delegation was the only non-Western one. Likewise, all the participants to the International Congress of Psychology, which took place between 1889 and 1948, were European and North American, except for the Japanese delegates, starting with Motora Yuijiro in 1905. In 1948 only a Chinese psychologist from Beijing, Oui Tsing-Chen, officially attended the Conference. This does not mean that no non-Western scholars at all attended these conferences, but, most of the time, they did it on a private basis. Besides, international political cooperation came to a halt in the 1920s and this impinged on the scientific life. Several countries where modern academic life was burgeoning, like India, Egypt, or China, could therefore not participate in the international scientific exchanges.

International cooperation resumed after 1945 under the supervision of the UNESCO and its International Social Science Council. The International Union of Anthropological and Ethnological Sciences was created in 1948, the International Sociological Association and the International Political Science Association in 1949, and the International Union of Psychological Science in 1950. Their goal was not only to bring together the existing national associations, but also to actually implement them where they did not exist. The non-Western nations had an important place in this process: they were becoming independent and needed scientific expertise to build modern states and societies. The UNESCO, moreover, played a crucial role in the promotion of non-Western cultures, and published several of their classics in literature and philosophy. It was committed to promote the equal dignity of all cultures and did so with the help of renowned social scientists (see Lévi-Strauss et al., 1952): human sciences, which had been instrumental in the colonization of non-Western people, had the opportunity to critically reflect on their function. For the last decades, the UNESCO and its associations have allowed non-Western scientists to play a more important role in the scientific life; it is still the case today: its *World Social Sciences Reports* still give non-Western voices the place they deserve and, under its supervision, non-Western scholars have taken part in international conferences and set up Asian, Arab, or South American research associations.

Likewise, nonstates actors have played an important role. Churches were instrumental in the acclimation of European disciplines at the nineteenth century. American missionaries taught psychology in China decades before it was part of the curriculum of national universities there. Admittedly their goal was not to introduce a scientific discipline per se but to foster a new conception of the self that, they hoped, would lead to a new work ethic. Other religious missions, like in Egypt, were truly involved in the dissemination of modern sciences and have been acting as intermediaries between the Egyptian scholars and their Western colleagues. Non-Western scholars and officials took the role of Western churches seriously. In Japan, where Japanese converts and Western missionaries had been instrumental in the creation of some of the major universities, the religious issue prompted a heated debate. Fukuzawa Yukichi (1835–1901), the father of Japanese scientific modernity and the founder of Keio University, was so convinced of the key role of religion that he advocated the formal conversion of Japan to a Christian state.

Other intellectual networks took an important part in the acclimation of human sciences and the empowerment of non-Western voices. Despite Marx's ethnocentric views, which can be found in some of his earlier texts, Marxism quickly spread in non-Western countries. Its influence grew beyond the political arena and reached the field of human sciences. One of the main reasons for this success is to be found in the ambivalent position of Marxism with regard to Western modernity, as it was both a direct outcome of this modernity and critical of its many shortcomings. This ambivalence was appealing to non-Western scholars who were aware that modernization was inevitable but sought a way to reassess the power relations underlying the diffusion of Western modernity. Indian historiography relied heavily on the Marxist point of view to deconstruct the English history of India. Whereas colonial works had stressed the role of local elites and had dismissed endogenous processes, Marxism helped a new generation of Indian scholars to pay attention to lower-social classes and the antagonisms that had shaped the building of the Indian nation. In Japan, likewise, Marxism gained influence in the human sciences in the 1910s and the 1920s as the Japanese were translating the debate on the birth of capitalism launched by Max Weber or Werner Sombart. It helped them to account for the class conflicts that were latent at this time and to address their country's special position in a system of global economic asymmetries. The military government ruthlessly cracked down on Marxists but they reflourished after 1945, as they had critical resources to analyze the rise of Japanese militarism as well as the numerous inequalities that the Japanese 'economic miracle' had not removed (Barshay, 2007).

The feminist movement played a similar role. At the juncture of politics and academy, it allowed for a quick dissemination of theoretical texts and empowered dominated voices from the South. Feminism has long history but was decisively reshaped in the West in the 1960s; it then became global through an internationalization of the political fight and the worldwide influence of American gender studies (Marx Ferre and Tripp, 2006). This has favored the transdisciplinary

circulation of theories, drawing from sociology, psychology, literary studies, etc. Worldwide connections were obvious, for gender-based dominations seemed to supersede determinations such as national and cultural identities. Yet the rise of 'global feminism' has not completely displaced the opposition between Western and non-Western countries. Many feminists from the South asked whether the narratives from the North could accurately describe the experience of women there. Some radically called into question the very possibility for such textual apparatus to give access to the subaltern women's voice (Spivak, 1988). The diffusion of feminist theories therefore gave rise to epistemological debates in which non-Western scholars intended to challenge the Western bias at the heart of human sciences: some radically dismissed any European-styled theory whereas others pleaded for pragmatic solutions.

Both Marxist and feminist networks highlight the role played by transnational diaspora in the diffusion of human sciences. Many non-Western Marxists have been moving between their country and the West, where they studied or, for some of them like the Arab Marxists, found shelter. This is also the case with feminism, Gayatri Spivak (1942–present), a Calcutta born scholar who teaches in New York, being probably the most famous. But transnational connections have allowed for important exchanges in other disciplines. Many of the Indian scholars, who founded the Subaltern and Postcolonial Studies, have taught and lived in the West. Their position not only contributed to the hybridization of Western and Indian history; it also allowed them to take a critical distance with their country's mainstream historiography. As they had more freedom to reevaluate the nationalistic discourse and the modernist bias on which Indian Marxist history was premised, the Subaltern historians reassessed the role of social classes previously dismissed as 'backward.' Likewise, many Arab scholars who took part in the postcolonial reevaluation of Orientalist history were Diaspora intellectuals, such as Anouar Abd-el-Malek (1924–2012), a Paris-based Egyptian Marxist, or Edward Said (1935–2003), who lived and taught in the United States. These Diaspora intellectuals were deeply familiar with the languages and culture of the West and, at the same time, felt 'out of place' there: 'outsiders as insiders' they turned this ambivalent position into a critical awareness of the European knowledge.

Politics of De-Westernization: 'Nation,' 'Socialism,' 'Culture'

Western human sciences prompted the global diffusion of political concepts and references, which, in turn, allowed for de-Westernization programs. The ideas of 'nation,' 'socialism,' and 'culture' have been among the most labile and influential ones: acclimated, they allowed for critical reflections on what human sciences could and should be outside of their original context.

The nation could not have been 'imagined' without human sciences. Indian rulers could not have turned a collection of kingdoms into a nation without the English statistics. Far from challenging the categories of the colonizers, the Indian administration endorsed their view of the society. Whereas castes had been rather fluid entities, they became fixed status into which Indian citizens were to be classified. Indian sociologist played a key role in this process. The discipline developed as an outcome of colonial anthropology without reassessing its underlying culturalist bias. The founding fathers of Indian sociology reified anthropological entities and developed an understanding of the Indian society based on conservative Hinduism and Brahmanism (Patel, 2010). India became a nation organized according hierarchies sociology had largely reconstructed.

Accordingly, many new independent East-Asian nations used colonial statistics to launch their modernization. In socialist countries, governments and anthropologists used colonial censuses to target 'backward' people: ethnic groups were to be identified and assimilated to the new society (Van Bremen et al., 2005). Ethnicity was to a large extent a creation of colonial administrators, for there was no homogeneous population behind the categories. Yet both the new national states and, surprisingly, the tribes themselves, began using these categories. The latters understood what they could gain from the statistical identification, as it gave them leverage to oppose assimilation policies or, on the contrary, to claim a fair share of the national income.

Socialism provides a second illustration of an idea that, once rooted outside the West, both favored the acclimation of human sciences and influenced de-Westernization programs. As said before, Marxist networks acted as early channels of scientific diffusion. After 1945, numerous non-Western intellectuals sided with the Communist parties, which had been involved in the anticolonial fight. Those who did not live in socialist countries used Marxism to address scientific asymmetries. In the Arab world, scholars such as Anouar Abd-el-Malek or Mohamed Talbi (1921 to present) used Marxist epistemologies to critically reread colonial scholarship. In Japan, likewise, Marxism allowed sociologists to oppose the American functionalist paradigm and offered critical perspective that enhanced the scientific creativity.

Besides, as many non-Western countries joined the socialist nations, socialism shaped the frame into which these states modernized and opposed Western hegemony. Various brands of Marxism provided the guidelines of the new human sciences. China offers the most striking illustration of this process. In 1952 most human sciences were targeted as 'bourgeois sciences.' The scholarly activity became state-controlled in the name of the edification of socialism. Scientists were discriminated, especially in paroxystic moments such as the '100 Flowers' or the Cultural Revolution, and saw their autonomy significantly restrained, which was detrimental to theoretical innovation. Sociology, for instance, practically shut itself to critical approaches and statistics became the only legitimate way to account for the society.

Not all human sciences were dismissed though. Linguistics was crucial to the elaboration of a socialist nation, as the renewal of the Chinese script was necessary for the largest part of the population to have access to the written language. Chinese scholars were nevertheless asked to severe ties with Western theories. They found inspiration in Soviet linguistics but, when the relations between the two countries deteriorated, had to find other paradigms. They rediscovered Chinese treatises and began elaborating their own brand of linguistics. International contacts resumed in 1979 when Deng Xiaoping

(1904–97) opened a new era of modernization and decided that the country had to catch up with Western sciences. Yet this did not lead to a complete re-Westernization of human sciences. Chinese scholars were still committed to find proper ways to account for their culture, as well as to take the specificities of socialism into account. This is, for instance, what led some sociologists to launch research programs premised on the idea of a specific 'socialist civilization' (Merle, 2004).

'Culture,' accordingly, decisively influenced de-Westernization programs. The idea of culture, as European ethnologists had elaborated it, spread through a variety of channels. Chinese ethnologists, for instance, created their own notion by drawing from traditions as different as the *Kulturkreislehre*, the Durkheimian School or the American diffusionism. All countries quickly assimilated the notion of culture as, in the nineteenth century, the Western scientific gaze was grasping them under this category. The idea was highly appealing to local rulers and scholars: it allowed them to assert a sense of fundamental difference with the West at a time of threatening Westernization. Folklorist educated in the West played a key role. They went to the remotest parts of the country to gather old tales, forgotten idioms and customs, and reconstructed a cultural legacy that was crucial for the nationalist narrative. Countries that had been among the first modernizers were also the first to assess the ancient nature of their culture. In Egypt, anthropologists reconstructed the pristine figure of the *Fellah*, as being immemorially linked to the Egyptian land. In Japan, likewise, the Westernization of the country went hand in hand with a rediscovery – which was partly a re-creation – of Japanese culture. Some recipes, martial arts, or drawing techniques had already been codified as 'typically Japanese' at the eighteenth century. This trend gained momentum with the importation of European anthropology and many social activities came to be redefined as belonging to the Japanese cultural legacy.

Culture easily allowed for counter-hegemonic critics. As it gave a scientific basis to the difference between Europe and other countries, non-Western scholars could legitimately claim that they were in the best position to study 'their own culture.' This argument became powerful after the decolonization, when Western researchers did not get an easy access to the field anymore and local ones pressed for significant changes in the anthropological discipline. More recently, 'culture' became a key word for new de-Westernization programs. Countries like Iran or Singapore reframed their political opposition to the West in culturalist terms. In the 1990s, the Singaporean government launched the 'Asian values' campaign to assert Asia's different political and cultural standards. The campaign led to attempts to build alternative sciences. Some Singaporean sociologists called to reframe Asian sociology, for, they argued, the European founders of the discipline were of little help to understand Asia's specific problems at the end of the twentieth century. Accordingly, the Iranian leaders tried to promote scientific and cultural de-Westernization programs after the Islamic Revolution. Under the label of the *Jahad-e-Daneshgahi* (scholarly Holy War) they intended to Islamize the Western epistemic frame. European human sciences had been acclimated under the Shah, when the country was to be modernized at any price. The revolutionaries logically sought to remove this symbol of cultural alienation. They had the universities' curricula rewritten and tried to find Muslim sources to reframe human sciences. The program nevertheless felt short of its promises. Iranian scholars, even the most loyal to the Revolution, were committed to European theories: they had already found ways to conciliate their Muslim culture with the promises of Western scientific enlightenment. Some paid lip service to the cause of the Islamic scientific revolution but, when it was possible, began to openly acknowledge the necessity to take Western human sciences seriously. As the reformist movement gained momentum, they finally came with some of the most innovative propositions to blend Islamic and Western theories (Mahdi, 2010).

Intellectual and Argumentative Strategies of De-Westernization Programs

De-Westernization programs prompted as many intellectual and argumentative strategies as there were different countries and time periods involved. Nevertheless, it is possible to gain a better understanding of these programs by subsuming them into four main (nonexhaustive) categories.

De-Westernization programs arose, first, from the *early reactions to European imperialism and intellectual hegemony*. In the Muslim world, from the 1850s on, scholarly reactions to the disruption of local knowledge followed two lines of reasoning that are still prevalent today. Some intellectuals claimed that Western scholarship was unable to grasp the specificity of the Islamic culture; the fact that it had been brought though imperial conquests was another important argument to disqualify this type of knowledge. Other scholars, on the contrary, argued that it was necessary to make the difference between the political acclimation of these theories and their heuristic value. For them, they could help the Muslims to get a better understanding of their civilization and to rebuild Islam. Conservative and reformist scholars differed when it came to what should be done to reshape the intellectual life, even though all agreed that they had to take human sciences seriously.

In Japan, as well, scholars began to reassess Western episteme in the first decades of the twentieth century. The country had gone through one of the swiftest scientific acculturations: the followers of the founders of Japanese human sciences began pondering on what had happened. Some argued that they should elaborate theoretical frames that fit the specificity of their society and, sometimes, browsed ancient Asian texts to find conceptual inspiration. Some scholars even developed the idea of an encompassing pan-Asian intellectual unity, from Tokyo to Istanbul, but it did not manage to challenge the European systems, as it was premised on the assumption of Japanese imperial supremacy.

In almost all countries, de-Westernization programs took place as Western epistemologies were reframing local knowledge. Yet these early attempts have no real unity except for the fact that they happened in the same historical context. Besides they had little direct effect, as scholars thought more important to understand Western human sciences than to challenge them. They were nevertheless important, because they show that non-Western intellectuals were perceptive of the epistemic reconfigurations of modernity and tried to curb them: they developed

arguments that, in the following decades, became resources their followers tapped into.

A second set of de-Westernization program was linked to the *decolonization of human sciences*. The implementation of national universities and research centers was an important step, and non-Western people, who had been the object of Western human sciences, became active subjects in their production. Accordingly, the nationalization of disciplines implied a rupture with their European origins and favored the recognition of scholars from postcolonial nations. There was a strong legitimacy to do so: human sciences had been instrumental in the colonial rule and a new scientific apparatus was therefore necessary to understand decolonized societies. Scholars began rereading the texts Western researchers had written on their country, with dramatic consequences sometimes. Orientalism practically ceased to exist when non-Western researchers asked why it had been incapable, during almost two centuries, to integrate the scholars coming from the very cultures it was studying. Anthropology, likewise, had to reassess its ethnocentric bias. Yet this critical introspection reinforced the discipline: Western and non-Western scholars came to work together and improved their understanding of non-Western societies. Such collaboration was easy to develop, for many Western anthropologists had taken part in the anti-colonial fight and knew the shortcomings of colonial sciences. This example also shows that, despite some attempts to fully replace Western epistemologies, the scientific decolonization, rather, led to reconsider them. The existing disciplines were not abolished, nor the type of rationality they were premised on: but, in terms of content, the way they accounted for non-Western cultures was significantly different.

Scientific decolonization was a strong motto in the new independent nations, but it soon faltered. Postcolonial states relied on modern knowledge to modernize their societies and could not completely severe ties with Western-styled sciences. Besides, the disenchantment with political decolonization impinged on the scientific one. The very scholars who had been truly committed to de-Westernization began to reconsider their positions. In the West, yet, intellectuals of the Diasporas, such as Edward Said and some Indian scholars based in the United States, revived the project of scientific decolonization under the guise of the postcolonial studies. They rephrased the debate that took place in the 1960s into the theoretical frame of the American academia at the then end of the twentieth century. They found new spaces for (post)colonial voices, at the margins of literary studies and human sciences, and could claim that scientific decolonization was still an unfinished journey (if not an unfinishable one).

A third type of de-Westernization programs has been premised on what can be called *priority disputes*. As they acclimated human sciences, non-Western scholars dug into local ancient texts to find equivalents of European concepts. This led them to 'go back to the classics' and to claim that the supposed novelty of human sciences could be traced back to the past of other civilization. Fei Xiaotong (1910–2005), one of the founders of Chinese sociology, compared Durkheim and Confucius in the 1920s: for him, Durkheim's notion of society, understood as a set of collective determinations, was similar to the emphasis that the Confucians had put on the commonality of human life. In the Arab world, likewise, sociologists compared European sociology with Ibn Khaldun's (1332–1406) theories and saw in the latter the true father of sociology. The comparisons did not always have the same function. In the first case, the contrast between Confucius and Durkheim was meant to introduce the latter's ideas to China: as Chinese readers were familiar with Confucius, the commentators of Durkheim hoped that they would gain a better understanding of the French sociologist. With Ibn Khaldun, the strategy had a distinct political tone. It implied that the modern sciences, which were supposed to express European superiority, were not as modern and not as European as they looked like. The Arab and Islamic civilization, the argument goes, had the same kind of intuitions earlier and deserved credit for their role in the rise of scientific modernity. Such priority arguments often mixed the two strategies to some extent though: Ibn Khaldun was also used to introduce modern sociology and Confucius to politically oppose the claim of European superiority.

Among all disciplines, psychology has probably been the most extensively reassessed in an historical light. Asian countries have traced the roots of *their* psychology to Confucius and the Buddhist Canon. The Indians have located it in the classical texts of Hinduism and Muslim scholars have written countless essays on psychology and the Koran. All claimed that the topics psychology apparently deals with (desire, fear, death, etc.) had already been addressed in their own traditions. Yet there are deeper reasons for this reconstruction. Western psychology was introduced in its experimental form, with the idea that a true understanding of the human mind has more to do with laboratory experiments than with symbolic questions. This hardcore epistemology came under strong attacks soon, including in the West, as it treated the psyche like any other material being. An alternative psychology soon emerged, which paid more attention to the role of language and history. For non-Western psychologists, it was an opportunity to reassess the role of culture in the formation of the self. They argued that the mind is structured by linguistic categories, which are not the same as in all languages. Besides, they claimed that family patterns, religions, or power relations variously shape the psyche. Their argument was scientifically and politically sound. It allowed them to challenge modern psychology and to rebuff the claim that the West had the key to the universal self.

A fourth set of de-Westernization programs has focused on the idea of *alternative or multiple modernity* (Parameshawar Gaonkar, 2001; Eisenstadt, 2000). As human sciences are a typical outcome of modernity, non-Western scholars argued that different types of modernity, and their corresponding scientific patterns, are possible. In its most radical version, this program intended to challenge the epistemological basis of human sciences. The aforementioned Singaporean program was premised on this line of reasoning; so were the ones some Chinese scholars developed from the 1990s on. They often originated in Asian universities, as many Asian countries had become as economically powerful as the West and could argue that they had developed their own modernity. For them, Asian modernity was different from the Western one: the Chinese and Japanese people were held less individualistic than the Europeans, and were supposed to have given rise to a significantly different type of society. The classical concepts that the founding fathers of human sciences had elaborated one century

before in Europe were therefore inadequate to the current Asian situation. Some Chinese sociologists, for instance, claimed that classical sociology was incapable to grasp China's entry into modernity, as it did not occur according to the liberal and capitalist scheme, but through a socialist and culturally distinct one.

These programs had different outcomes. It proved difficult to prompt a complete shift of paradigm and Western notions continued to loom in the background of the new human sciences. Besides, many non-Western scholars were skeptical. For them, total de-Westernization was inspired by conservative politics and, on a scientific level, was not as creative as some had hoped. Some scientists argued that many positive outcomes of modernity were still missing in Asia and that it was too early to dismiss the Western experience. Other scholars began to work on more realistic de-Westernization programs: for them, the point was not to replace the European human sciences but to accommodate them to non-Western situations. The European scientific apparatus should be retained because it is flexible enough to be transformed from the inside, with non-Western scholars creating new concepts to account for their cultures. Current developments in Chinese sociology point to that direction: Chinese scientists try to hybridize Western concepts and to promote new ones that can grasp the specific modernity of China.

To some extent, the debate about alternative modernities has echoed the reflections on postmodernity that developed in North American universities in the 1980s. Not only the Japanese or Chinese, who studied there, but Iranian scholars too, have been influenced by these questions. Postmodernity implied that the Western epistemic centrality had been overcome. Besides, postmodern thought has been premised on the notion that no narrative is universal, not even the scientific one. European Western sciences, accordingly, are one narrative among others, with no intrinsic superiority. Many conservative Iranian scholars, albeit politically adverse to the United States, took part in the debate and concluded that the modern scientific apparatus is nothing but the result of the specific cultural conditions of Europe. The fact that American scholars had originally elaborated postmodern thinking, seemed to give more credit to the idea. If the postmodern debate has bloomed in the field of literary studies more than in the human sciences, it was nevertheless significant enough to legitimate the idea that the latter were an outcome of Western modernity with no claim to general validity.

The de-Westernization of human sciences is as old a program as their very diffusion of the human sciences. Yet it has gained momentum in the last decades, as the centrality of the West was contested. Following the postcolonial debates, the scientific community came to better associate Western and non-Western researchers. Accordingly, there has been a realization that Western epistemologies, despite their worldwide diffusion, were not the only way to account for the reality: different epistemic patterns used to prevail among non-Western cultures and could reframe alternative scientific systems one day. It is nevertheless too early to conclude that these programs have significantly challenged the global scientific asymmetries. The United States and Europe are still hegemonic, with around 90% of all the articles of human sciences written between 1998 and 2007. Despite the significant rise of the publications by Asian and South American scientists (respectively +74 and +46%), the Western share has recently increased. Moreover local and regional collaborations have decreased, as more and more non-Western scholars now work with their Western colleagues and/or in a Western language (Gingras and Mosbah-Natanson, 2010). Countries like India or China, who intend to become major scientific players, continue to train their scholars in Western universities and have them write in English.

This ambivalent situation indicates that the idea of de-Westernization is today at a crossroad. On the one hand, the exhortation to 'provincialize Europe' and the promotion of epistemic pluralism, are enjoying unprecedented influence. On the other hand, Western scientific hegemony has reinforced and, statistically speaking, appears barely contested. The current critics against the West might hint less at the impending end of the European and North American scientific centrality, than at its continuity in a new period of globalization. The situation also exemplifies the different outcomes of the de-Westernization programs launched in the last decades. The most radical attempts to replace Western human sciences have not managed to actually implement alternative epistemologies. Others sought to reframe human sciences from the inside and were more successful. They argued that, as Western modernity has reshaped the world, it is important to use the tools this modernity has brought to make sense of the current situation. Besides, they stressed that Western human sciences are politically cogent, for they allow critical insights, including on what has made the West dominant. In this respect, the apparently abiding centrality of Western human sciences may hide significant reconfigurations at a deeper level.

White Collar Crime: Recent Trends and Debates

Michael L Benson, University of Cincinnati, Cincinnati, OH, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Recent trends in white-collar crime include a shift in theoretical orientation to opportunity and choice perspectives, a rising interest in the psychology of white-collar crime, research focused on the role of white-collar crime in the global financial crisis, and a continuation of research interest on white-collar offenders' use of neutralizations and accounts. Debated issues include the efficacy of different regulatory styles in controlling white-collar crime, gender and white-collar crime, and the applicability of low self-control theory to white-collar offenders.

Introduction

Although the problem of how white-collar crime should be defined is an old one, no summary of developments in this area, recent or otherwise, can avoid it. Definitions of white-collar crime can be divided into two main groups – offender based and offense based. Following Sutherland (1949), the offender-based approach defines white-collar crime in terms of the social, economic, and occupational characteristics of offenders. One well-regarded definition, for example, defines white-collar crime as "violations of law to which penalties are attached that involve the use of the violator's significant power, influence, or trust in the legitimate economic or political institutional order for the purpose of illegal gain or to commit an illegal act for personal or organizational gain" (Reiss and Biderman, 1981). This definition specifically requires that the offender have and use 'significant power, influence or trust in the legitimate economic or political institutional order' in committing his or her violation of the law. It follows that individuals lacking these characteristics cannot be white-collar offenders. Offense-based approaches ignore the characteristics of the offender and focus instead on the nature of the act. The most well-known offense-based definition was proposed by Edelhertz (1970), who defined white-collar crime as an "illegal act or series of illegal acts committed by nonphysical means and by concealment or guile to obtain money or property, to avoid loss of money or property, or to obtain business or personal advantage." The key element in this definition is the stipulation that the offense be committed by 'nonphysical means and by concealment or guile.' Because the characteristics of the offender are not included as part of the definition, individuals from all walks of life could, in theory, commit a white-collar crime.

Both types of definitions have their respective strengths and weaknesses. The offender-based approach draws attention to the serious offenses committed by high status individuals that are all too often ignored in mainstream criminology, but it also arbitrarily restricts focus to just these offenses while ignoring similar offenses committed by individuals from less elevated social backgrounds. The offense-based approach not only avoids this arbitrary restriction, but it also broadens the conceptual terrain of white-collar crime to such a degree that the term loses its significance as a focus of theory and research. In practice, the offense-based approach often misses the crimes of the powerful and substitutes in their place small-time offences, such as frauds by appliance repairmen and employee theft by retail clerks. Benson and Simpson (2009) note that although there is a long-running and vigorous debate over which definition is best, the two approaches are not necessarily mutually exclusive. The white-collar offenses committed by high status individuals rely on the very means identified by Edelhertz's (1970) offense-based definition – concealment, guile, and deception. Researchers following Edelhertz's approach could study high status individuals if they would take the time and effort to find them. This often does not happen reflects a failure of the researchers rather than a logical weakness of the offense-based approach. Nevertheless, the debate is not yet resolved and any summary of recent developments in white-collar crime must recognize that different definitions are used in the field, and that this influences the types of findings and trends that one observes.

Trends

Recent trends in the study of white-collar and corporate crime can be divided into two broad categories: (1) developments in substantive areas of focus and (2) evolution in theoretical perspectives. With regard to substantive areas of focus, scholarship in white-collar crime often tends to follow current events and to be directed toward the latest social, political, or economic scandals, because such scandals often involve white-collar type offending in one way or another. Thus, spurred by the global financial collapse, a considerable amount of research attention has been focused recently on national and international financial- and market-based crimes that are thought to have contributed to, if not actually caused, the current crisis. Theoretically, scholarship on white-collar crime has been evolving in directions that have obvious implications for each other and may eventually merge. First, there is the increasing dominance of the opportunity or choice perspective over the traditional criminological theories as the preferred explanatory framework for understanding white-collar offending. Secondly, there has been a surprising flurry of interest in the psychological and individual level attributes of white-collar offenders compared with other types of offenders and law-abiding citizens. Finally, research on how white-collar offenders' use of neutralizations and accounts may be shaped

by gender and social class has reinvigorated this traditional area of interest.

Mortgage Fraud, Financial Crimes, and the Global Financial Crisis

The financial crisis that hit the United States in 2008 as a result of the collapse of the housing market has provoked considerable and ongoing commentary (Levi, 2010a; Benson, 2010; Shover and Grabosky, 2010). It seems relatively clear that the global financial crisis was sparked in part by massive fraud and unconscionable risk-taking in the mortgage and finance industries during the 1990s and early 2000s (Financial Crimes Enforcement Network, 2006; Partnoy, 2003). But it is unclear whether the financial crisis itself necessarily led to more white-collar offending. Levi (2010a), for example, argues that the financial crisis was not really global. Rather, it hit some nations much harder than others. He further contends that rather than sparking more white-collar crime, the financial crisis may simply have brought to light what was already happening. The distribution and potential collateral consequences of mortgage fraud has provoked research on ecological variations in the prevalence of mortgage fraud in neighborhoods (Carswell and Bachtel, 2009), as well as research on whether the high rates of bankruptcies that resulted from the collapse of the housing market led to increased street crime in disadvantaged neighborhoods (Baumer et al., 2012).

Much of the research on mortgage fraud has focused on the subprime mortgage market, where fraud seemed to be most rampant. Findings indicate that several different factors were involved in the explosion of mortgage fraud, including inadequate regulation, the proliferation and overuse of alternative loan products, and a general lack of accountability in the mortgage industry (Nguyen and Pontell, 2010). These factors permitted unscrupulous mortgage brokers and profit-hungry lenders to engage in predatory lending, a form of lending in which loan makers and their associates use deceit to push financially ill-advised loans on unsuspecting borrowers. Such loans end in default at a much higher rate than traditional loans.

Although mortgage fraud was rampant, by itself this type of fraud might not have had such far-reaching and detrimental financial effects had it not been accompanied by other developments. The real problem involved changes in the mortgage and financial industries, in particular the practice of pooling mortgage loans and treating them as securities. These mortgage-backed securities or collateralized mortgage obligations (CMOs) as they are also known, were put together by large Wall Street financial firms and sold to investors. Under this system, banks and other lenders no longer had much incentive to carefully screen loan applications and to approve only those that were financially viable. Rather, it made more sense to make as many loans as possible regardless of the financial status of the borrowers because even bad loans could be off-loaded to the market for CMOs. Unfortunately, CMOs are so complex that it is exceedingly difficult for even highly experienced investors to evaluate the risks associated with them, making it easy for those who market CMOs to fraudulently misrepresent or conceal their true value. This apparently is exactly what happened in many cases; when the housing bubble finally collapsed in 2008 and borrowers began to default, many CMOs lost significant value overnight, threatening the financial security of their holders.

A central theme of all of the recent research on the role of white-collar crime in the various financial crises that have rocked the US economy in the past two decades has been the inadequacy of oversight and regulation of the corporate sector. Regardless of whether the focus is on fraud in mortgages, mutual funds, investment banks, energy companies (Enron), or telecommunication giants (WorldCom), a root cause of the scandals in all of these different arenas has been the lack of effective regulation and supervision and the over-reliance on 'private market discipline' to control abuses (Levi, 2010a). In effect, ineffective regulation creates criminal opportunities for white-collar offenders.

Opportunities and Choices

Although virtually all of the major theoretical perspectives in criminology have been applied at one time or another to white-collar or corporate crime (for a brief review, see Benson and Simpson, 2009), most have not fared well in regard either to their explanatory scope or their ability to motivate a sustained body of empirical investigations. To apply traditional criminological theories to particular instances of white-collar crime often requires 'extensive conceptual acrobatics' (Simpson, 2013); and after the theory is fitted to its procrustean bed, its usefulness as a general explanatory tool seems diminished. Thus, the field has witnessed a number of one-shot efforts in which traditional theories are applied once to a particular case or sample but the results are never replicated or extended by others in any sustained way. One exception to this general pattern involves the 'low self-control' theory, which has been the subject of a notable number of empirical and theoretical investigations, most of which have been highly critical of the theory. Since the scholarship around the low self-control theory has been largely confrontational (as opposed to confirmatory), it is discussed in the section on current debates.

However, unlike the largely desultory approach to white-collar crime prevalent in traditional criminological circles, the opportunity or choice perspectives have gained traction and appear to be generating sustained interest among white-collar crime scholars (Shover and Hochstetler, 2006; Benson and Simpson, 2009). The double-barreled nomenclature used here – 'opportunity or choice' – reflects the differing points of emphasis found in this perspective. As advanced by Benson and Simpson (2009), the 'opportunity' perspective draws attention to situational conditions that either facilitate or impede particular types of white-collar offending. This perspective rests on the assumption that the presence of criminal opportunity is an essential causal element in all offending. A criminal opportunity arises whenever a suitably motivated person or group of persons recognizes or perceives that a suitable target is not adequately guarded. In regard to white-collar crime, the term 'suitable target' is not meant to be restricted to a person who can be attacked or a physical object that can be stolen or damaged. Rather, targets are conceived more broadly and flexibly to include situations in which an individual or group of individuals can pervert or distort

legitimate economic business or professional activities so as to illegally benefit themselves. For example, the buying and selling of securities is a legitimate economic activity that can be perverted when a corporate insider trades shares of his or her own company on the basis of nonpublic material information. Here, the activity of trading securities is the target. If that activity is not well regulated and supervised (i.e., guarded) by governmental entities, then it becomes a suitable target by means of which a potential offender can take advantage of others to enrich himself or herself.

In regard to white-collar crime, criminal opportunities arise or become available to potential offenders as a result of their holding certain occupational positions. The occupational position gives the offender 'legitimate access' to some situation or opportunity in which the offender can advance his or her own interests at the expense of other individuals, organizations, or the market in general (Benson and Simpson, 2009; Felson and Boba, 2010). For example, by virtue of their positions in the health care system, physicians have access to various public and private health care insurance systems. Because of this legitimate access, physicians can submit fraudulent claims for payment for health care services rendered (Sparrow, 1996). As another example, by virtue of their positions, the owners or highly placed executives in certain types of companies can conspire together to set prices or rig bids in violation of antitrust laws (Geis, 1977).

The degree to which occupational positions create or make available opportunities for white-collar crime depends on the laws, regulations, and rules governing occupations, industries, and types of economic activities. As laws or regulations evolve or change, opportunities for white-collar crime expand or contract. White-collar crime scholars have investigated numerous examples of the interplay between changing regulatory regimes (and especially deregulation) and the expansion or maintenance of criminal activities in various industries or services, including the thrift industry (Calavita et al., 1997), the health care system (Sparrow, 1996), the accounting profession (Coffee, 2002), and recently the mortgage industry (Nguyen and Pontell, 2010), to name a few. Indeed, recent and historical research on white-collar crime suggests a general conclusion presaged by Sutherland (1949) – that some form of white-collar crime can be found in all industries and occupations and the degree to which it is present depends, to a great extent, on the results of the political process that produces the structure and level of enforcement of regulatory regimes and criminal laws (Shover and Hochstetler, 2006).

Criminal opportunities only result in actual crimes, however, when someone decides to take advantage of them. Thus, the second term in the 'opportunity or choice' perspective draws attention to the reality that opportunities are not self-activating. Rather, they must be 'acted upon' by actors who make choices. Contemporary theory conceptualizes these choices as being made by cognitively astute rational actors, who weigh the costs and benefits of both legal and illegal lines of action before deciding to engage in white-collar crime (Shover and Hochstetler, 2006; Paternoster and Simpson, 1993; Piquero et al., 2005). Shover and Hochstetler (2006) argue that tempted or criminally predisposed individuals are attracted to what they call situations of 'lure.' Lure is similar to what routine activity theorists call suitable targets or criminal opportunities, but it is a broader, more economically oriented concept because it is not limited to static persons or things that an offender can attack or steal. Rather, it includes situations that provide actors with opportunities to advance their own interests – that is, to get ahead in some way, whether it is in a personal financial perspective or in the sense of improving the bottom line of a business, at little or some acceptable level of cost. For example, illegal undocumented immigrants are a source of lure, because they could be exploited by unscrupulous employers as a cheap and compliant source of labor who can be made to work under conditions and rates of pay that would not be tolerated by naturalized or native-born workers (Shover and Hochstetler, 2006). Contemporary research focuses on how the evolution and enforcement of criminal laws and administrative regulations, as well as the structure and standard practices of industries and markets, create criminal opportunities, and on how those opportunities affect or pattern the choices made by actors (Shover and Routhe, 2004).

Psychology and Individual Differences

Over the past two decades, criminology has taken a decisive turn toward individual differences, especially in regard to psychological and cognitive characteristics, as important explanatory factors in the etiology of criminal behavior. The importance of individual differences has been made apparent by the increasingly relevant research of biosocial criminologists, as well as the theories and findings of life-course and developmental criminologists. Yet, as Levi (2010b) notes, until quite recently, the practitioners of the biosocial perspective on crime showed little interest in white-collar crime or white-collar offenders; and white-collar crime scholars have returned the favor by showing little interest in life-course, developmental, or biosocial theory (Piquero and Benson, 2004). Indeed, white-collar offenders have long been assumed to be basically normal people who do not suffer from the psychological or personal pathologies that seem so common among street offenders (Coleman, 1989; Spencer, 1965; Sutherland, 1949). For many years, the only psychological or personality characteristic of white-collar offenders that provoked much interest was their seemingly total resistance to any attempt to define their activities as crimes (Benson, 1985; Maruna and Copes, 2005). Other than their tendency to rationalize and excuse their crimes, the psychological makeup of white-collar offenders was not thought to be an important dimension of white-collar crime.

The assumptions that white-collar offenders are psychologically normal and that individual differences have little or nothing to do with white-collar crime are now being called into question. A small but growing body of theory and research has begun to suggest that certain psychological characteristics may both facilitate white-collar crime and be more common among white-collar offenders than the general population. Oddly enough, this surge of interest in individual differences and psychology may have been sparked, at least in part, by the contention that there is nothing special about the etiology of white-collar crime and that for theoretical purposes, the whole concept of white-collar crime should be abandoned (Hirschi and Gottfredson, 1987). The developers of the general

theory of crime argued that white-collar crime is caused by the same factor that causes all other forms of crime – low self-control. Although most white-collar crime scholars vigorously dispute this claim (Benson and Moore, 1992; Yeager and Reed, 1998), it did lead some researchers to consider whether other psychological characteristics might nonetheless play a role in white-collar offending. For example, the psychological characteristic of 'desire for control' has been implicated in corporate offending (Piquero et al., 2005). The desire for control refers to a general wish or need to be in control of everyday events in life. Piquero et al. (2005) suggest that the strength of an individual's desire for control, influences the interpretation of rational choice considerations in regard to crime; and that the desire for control may lead to white-collar offending by businesspeople in an effort to reduce uncertainty in the business environment.

There are theoretical reasons for thinking that certain types of people may be more amenable to white-collar crimes than others. For example, theoretically it can be argued that since almost all white-collar crimes depend in one way or another on deception (Benson and Simpson, 2009), people who are capable of and are not troubled by the deceiving of others, will be better suited to white-collar crimes than people who have a difficult time fooling others or who feel the pangs of conscience when they lie and deceive. Although there are to date no studies that have explicitly examined deception as a trait related to white-collar crime, studies have found differences between white-collar offenders and others on traits that conceivably may be related to deception. An early study by Collins and Schmidt (1993) compared a sample of persons who had been convicted of white-collar crimes to a matched control sample of noncriminal white-collar employees on several personality scales. Offenders differed from nonoffenders on two dimensions: social conscientiousness and social extraversion. Conscientious individuals are dependable, responsible, rule-abiding, honest, motivated to high job performance, and committed to civic and social values. White-collar offenders seem to be less likely to display these traits than their law-abiding counterparts. Social extraversion refers to one's popularity and ability to navigate well in social situations. Collins and Schmidt (1993) speculate that people with outgoing personalities may compete well for higher level jobs where they are exposed to white-collar criminal opportunities.

More recently, efforts have been made to apply standard personality assessment tools to white-collar offenders (Walters and Geyer, 2004; Ragatz et al., 2012). One of the best-known assessments, the Psychological Inventory of Criminal Thinking Styles, has been used to compare the criminal thinking styles of white-collar offenders with that of other types of offenders. Before discussing the results of these investigations, however, it is important to note that this research suggests that care is needed in identifying whom to count as a white-collar offender. Indeed, there appear to be two types of white-collar offenders: (1) individuals who commit only white-collar crimes, called 'white-collar only offenders' and (2) individuals who commit both white-collar and non-white-collar crimes, called 'white-collar versatile offenders.' White-collar versatile offenders appear to be distinctly different from their counterparts who commit only white-collar type offenses, in regard to their lifestyles and criminal thinking patterns (Walters and Geyer, 2004; Ragatz et al., 2012). Ragatz and colleagues found that white-collar offenders tend to score lower than non-white-collar offenders on criminal lifestyle measures, but they score higher on measures of psychopathology and psychopathic traits. Indeed, a number of researchers have begun to focus on so-called successful psychopaths (Gao and Raine, 2010; Babiak et al., 2010; Babiak and Hare, 2006). Unlike most psychopaths who suffer from cognitive deficits, successful psychopaths manifest both psychopathic traits (glibness, manipulativeness, callousness, and lack of emotion) and enhanced neurobiological functioning and cognitive skills. In theory, these individuals have the cognitive and social skills necessary to use covert and deceitful methods to pursue their goals in ways that are not obvious to others and that sometimes involve undetected white-collar crimes. In addition, successful psychopaths are not burdened by moral qualms about obeying the law or by normative expectations not to hurt others unnecessarily. They are clever and unconstrained by ethical scruples. While this line of research is still in its infancy, it nevertheless adds an important new dimension to the choice perspective by providing a theoretical means to explain why similarly situated persons make different choices in regard to white-collar crime opportunities.

Neutralizations and Accounts

Even though it was originally developed to account for juvenile delinquency, neutralization theory has for many years had a receptive audience among those who study organizational and white-collar offending (Maruna and Copes, 2005). Investigations and explications of particular types of white-collar crime often devote considerable attention to detailing the linguistic mechanisms used by the perpetrators to justify, excuse, or account for their particular offenses (Benson, 1985; Conklin, 1977). Recently, however, researchers have begun to explore new questions about neutralizations that extend beyond merely identifying and describing their use by white-collar offenders. For example, researchers have begun to explore how the construction and use of neutralizations and accounts are influenced by gender and social class (Klenowski et al., 2011; Vieraitis et al., 2012; Willott et al., 2001). Stadler and Benson (2012) compared the use of neutralizations by white-collar offenders to those of other types of offenders and found surprisingly few differences. The significance and generalizability of the findings of this new body of research for white-collar crime, however, is questionable for methodological reasons. Some of the studies are based on relatively small samples of offenders who have been convicted of relatively pedestrian forms of white-collar crime, such as minor kinds of fraud, low-level embezzlements, workplace related offenses, and identity theft. Others are based on scenario studies of MBA students. Absent from these investigations are the professionals and corporate executives responsible for the most serious white-collar offenses, such as health care fraud, accounting fraud, antitrust violations, and securities violations. There remain only a very few studies of neutralization practices among upper class elite offenders.

Debates

Prevention and Control

Since many of the most serious forms of white-collar crimes are committed by or within business organizations, a significant amount of scholarly attention has focused on the most effective way to control these organizations. The regulation of business activities has a long and controversial history in the United States and in many other developed nations. In the United States, over the past few decades there has been a shift away from what is known as 'command and control' regulation to 'responsive regulation' (Shover and Routhe, 2005; Simpson, 2013). Command and control regulation takes a legalistic approach to the problem of controlling business organizations. In this style of regulation, regulatory agencies promulgate rules and then mechanically enforce them by imposing sanctions for noncompliance. Regulators see regulated entities as being driven solely by the amoral pursuit profit and as adversaries who will comply with regulatory directives only under the threat of state-imposed sanctions. While there is some evidence that the threat of sanctions works, the command and control approach also appears to foster the development of cultures of resistance and a minimalistic approach to compliance among regulated entities. Over time, the antagonistic relationship between regulators and the subjects of regulation raises the costs of oversight and reduces its effectiveness.

The command and control approach to regulation, with its emphasis on punishing violations in order to achieve greater compliance through deterrence, began to fall out of favor in the 1980s. Taking its place was a more flexible approach to enforcement called responsive regulation (Ayres and Braithwaite, 1992). This approach to regulation assumes that most business firms want to comply with regulations and fail to do so only because they are either not well-informed about their regulatory obligations or are simply unable to comply because of lack of technical or financial resources. In other words, firms are considered to be trustworthy and willing to self-regulate if treated with fairness and understanding by regulators. Noncompliance is seen as evidence of a problem that needs to be fixed rather than as a violation that needs to be punished. The role of the regulator is to educate and assist firms in their efforts to comply, and as long as firms are seen as making efforts in good faith toward compliance, sanctioning is unnecessary. Sanctions may eventually be imposed on firms who are obstinate in their noncompliance and who refuse to cooperate with regulators , but under responsive regulation, control through punishment is viewed as a last resort rather than the first option.

As with the command and control approach, the responsive regulation approach also has its success stories but the relative effectiveness of the two approaches is still a matter of debate. Critics of the flexible approach argue that it gives corporations too much influence over regulatory regimes and in the end fails to adequately protect the public interest. On the other hand, deterrence-based regulation is criticized for alienating the business community and for stifling productivity and innovation, which also harms the interests of the general public.

Gender

The study of women and white-collar crime represents both an emerging trend and an old debate shifted to a new domain. In the 1970s, the subject of women and crime became a hotly debated issue. Some scholars saw signs that the 'gender gap' in crime (that is, the difference in the prevalence of men and women in involvement in crime), which has always been large, was in the process of diminishing as a result of the Women's Movement and the greater social and economic equality that it was bestowing on women (Simon, 1975; Adler, 1975). As women attained social equality with men, it was thought that they would start to behave more like men, including getting more involved in crime. Others said that except for minor property offenses, such as shoplifting, the gender gap was not closing at all; and also argued that women's offenses were more often committed out of desperation rather than for enhanced social power.

A similar sort of debate is now going on in regard to women and white-collar crime. As with almost all other forms of crime (excluding only prostitution), women are less involved in white-collar crime than men. However, as more and more women enter and assume leadership positions in the corporate world, their level of involvement may increase. Dodge (2009) argues that in order to rise in organizational hierarchies women have had to become more like men in regard to aggressiveness and risk-taking. In her view, women's involvement in white-collar crime is and will continue to be on the rise as women's occupational opportunities increase. Other scholars are not so sure. The opposing view holds that even though women have made great strides in the workplace, they are nevertheless still marginalized at the higher levels of the corporate world. Even when women occupy positions of power, they are still usually excluded from the social networks that orchestrate and carry out large-scale corporate crime schemes. Some research suggests that, as with street crimes, women play subsidiary and minor roles in most corporate crimes. In addition, some argue that for both social and biological reasons, women are guided by different focal concerns than men and as a result, they are less likely than men to engage in white-collar crime even when they have the opportunity (Steffensmeier et al., 2013). When women do commit white-collar crimes, research suggests they usually do so for different reasons than men and they interpret their crimes differently from men (Daly, 1989; Klenowski et al., 2011).

Applicability of Low Self-Control Theory

Low self-control theory was developed by Gottfredson and Hirschi (1990). Although it has been applied primarily in regard to ordinary street crimes and offenders, Hirschi and Gottfredson (1987) controversially claimed that it also applied to white-collar crime and to white-collar offenders. In brief, the theory posits that at the individual level, the fundamental cause of all criminal behavior is low self-control. Low self-control refers to a behavioral propensity to pursue one's individual desires and pleasures with little consideration for long-term consequences or for the effects of one's behavior on others. People with low self-control are impulsive and insensitive, and when they encounter a criminal opportunity that

can satisfy their desires, they are likely to take advantage of it without concern for the potential long-term consequences of their actions. Hirschi and Gottfredson (1987) made a couple of controversial claims regarding white-collar crime, including (1) that is relatively rare and (2) that the demographic distribution (age, sex, and race) of these crimes is the same as it is for other forms of crime, which would imply that they all result from similar underlying causal processes.

With only a few exceptions (Herbert et al., 1998), the response to Gottfredson and Hirschi has been largely negative (Steffensmeier, 1989; Benson and Moore, 1992; Yeager and Reed, 1998). Critics have argued that Gottfredson and Hirschi based their assertions on flawed analysis of faulty data. Further, they have argued that white-collar crime is not rare but widespread and that its demographic distribution looks nothing like that of ordinary street crimes (Benson and Kerley, 2000; Wheeler et al., 1988). Finally, the organizational location of much white-collar crime renders the whole focus on individual level characteristics misguided (Yeager and Reed, 1998; Simpson and Piquero, 2002). Organizational or corporate crimes often involve groups of people who play different roles and who may participate in the offense for different periods of time. Indeed, the people involved in organizational criminal conspiracies may change over time, such that while any particular offense may be continuous over time, the offenders involved in it are not. In these cases, it seems difficult to attribute individual involvement in corporate crime, which varies over time, to stable underlying traits which supposedly remain constant over time. Rather, for organizationally based crimes, the causes of involvement seem more likely to arise out of externally generated pressures for performance rather than out of individual levels of self-control.

Conclusions

The study of white-collar crime has long been marginalized in criminology and it is likely to remain so in the future (Simpson, 2013). Nevertheless, recent developments suggest there is some potential for it to move closer to the mainstream. These developments pertain most directly to shifts in theoretical focus. As white-collar crime scholars have adopted the 'opportunity and choice' perspective to organize their research, their investigations have become more relevant to and congruent with current trends in mainstream criminology. Opportunity theory as applied to white-collar crime fits well with the approaches taken by situational crime prevention specialists, in that it draws attention to opportunity structures as important causes of criminal events. In regard to choices, the greater focus on individual differences and on life-course trajectories in white-collar crime also resonate well with the concerns of more traditional criminologists and with the rising biosocial perspective. Indeed, one could argue that white-collar crime scholars are playing an important role in expanding and deepening the study of opportunities, choices, and individual differences. For example, within traditional criminology, criminal opportunities are conceived in terms of the availability of physical targets and lack of guardianship, but white-collar crime investigations suggest that conceptualizations of opportunity need to be broadened to recognize that they can also arise out of legitimate economic and occupational activities. Another example of the potentially salutary outcomes of recent white-collar crime scholarship involves research on individual differences, especially those related to psychological and cognitive characteristics. Within traditional criminology, the temperamental characteristics of offenders are usually conceived as deficits or negative attributes. Offending is seen to arise out of the offender's cognitive or neuropsychological deficits, which make it difficult for him or her to succeed in conventional institutions such as school, work, and marriage. Recent research on white-collar offenders, however, raises the intriguing possibility that some offenders may not suffer from neuropsychological deficits. Rather, they may have enhanced cognitive functioning that actually facilitates white-collar offending. If this line of research continues to bear fruit, it suggests that the connection between temperament and crime will need to be reconceived.

White, Gilbert (1911–2006)

James L Wescoat Jr., Massachusetts Institute of Technology, Cambridge, MA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Gilbert F. White (1911–2006) is variously known as the "father of natural hazards research," "father of floodplain management," and all-around leader of the environment-society branch of geography in the United State during the twentieth century (Wescoat, 2006). These father-figure references convey the regard in which White has been held for his mentoring of two generations of colleagues and students as well as for his pioneering research on water resources, natural hazards, and environmental management. White's seven decades of creative work, beginning with policy analyses in the Franklin D. Roosevelt administration in the 1930s and concluding with reflective essays on environmental stewardship in the early years of the twenty-first century has produced a rich historiography of appraisals. The first section of this article reviews the historiography of previous assessments of White's research, from an early festschrift (Kates and Burton, 1986) to theoretical debates (Wescoat, 1992), an autobiographical essay (White, 2002), and memorial reviews following his death (Kates, 2011). The second section of the article rereads White's research contributions in different periods of his career, underscoring the relationships among research subjects, ethical concerns, and contributions to the field of environmental geography.

Historiography of White's Contributions to Water and Hazards Research

Commentators have reviewed the major themes in White's work in several different ways. His most widely perceived contributions were in the fields of water resources and natural hazards research. However, the first broad assessment that came in the form of a festschrift presented White's research contributions under 12 broad headings (Kates and Burton, 1986: p. xi):

- Public water supplies
- Floodplain management
- Natural resources
- International resources and environment
- Arid lands
- River basins
- Decision making
- Geographic education
- Weather and climate modification
- Environmental perception
- Environmental hazards
- Energy

This list appears diffuse, but the festschrift editors boiled down their appraisal to three main scholarly contributions to water, hazards, and environmental research: (1) the concept of human adjustment; (2) the theoretical and practical range of choice; and (3) the role of perception in decision-making (Kates and Burton, 1986: p. xii). They showed that these three ideas were interrelated with one another in a research framework that focused on decision-makers' perceptions about the range of choice among alternative adjustments to resource scarcity and hazards. This research framework helped bring about a shift from thinking of flood losses as 'Acts of God' to regarding them as consequences of individual and collective action.

As elaborated below, this early appraisal followed shortly after intense criticisms of White's natural hazards research, articulated in part as book reviews of *The Environment as Hazard* (Burton et al., 1978), which characterized his approach as behaviorist, scientistic, atheoretical, politically silent about the roles of power relations and injustice, and insufficiently critical of technocratic ideologies and methods of water engineering (e.g., Hewitt, 1983). Ironically, White's earliest research had directly challenged those structural engineering approaches to flood control on empirical, economic, and policy grounds (e.g., White, 1942/1945); but it had not addressed explicitly the underlying social and political structures and processes that drove them, such as race, gender, poverty, and class. A significant yet less vocal scholarly criticism questioned White's emphasis on applied policy-relevant geography compared with basic research (White, 1972).

A philosophical appraisal addressed these challenges by examining White's contributions in relation to four main themes in the pragmatism of John Dewey, citing direct and indirect influences (Wescoat, 1992):

Dewey	*White*
Precariousness of existence	Hazards perception
Logic of inquiry	Expanding the range of choice
Learning from experience	Behavioral geography
Discourse and democracy	Public policy

White had mixed reactions to this theoretical interpretation, questioning its utility for people and places (pers. comm., 1993 onward). He grew more positive about theoretical debates over time as graduate students and others worked more consciously with or in opposition to pragmatist approaches (e.g., White, 1997). White continued to challenge scholars about what difference their work can make for environmental and human well-being, which is a core query in pragmatism. White and colleagues also gave increasingly explicit attention to societal

driving forces in human vulnerability to natural hazards, and that research has become increasingly mainstreamed in the field (Cutter, 2006; White et al., 2001; Wisner, 2003).

The most deeply personal study of White's work and life came in a biography by Robert Hinshaw (2006) that was completed in the year White died. Written by a scholar, Quaker, and multidecadal friend, Robert Hinshaw's *Living with Nature's Extremes: The Life of Gilbert Fowler White* strives to present the inner deliberations as well as outward manifestations of White's research, gleaned from numerous interviews and personal diaries. It is perhaps no accident given the complexity of this task that the volume has *three* concluding chapters: 'Gilbert White: the Man', 'Gilbert White: The Legacy', and 'Epilogue'. Personhood is a vital dimension of all scholarly lives, but it has been particularly underscored in White's case. Hinshaw's portrait focuses on moral convictions, social values (humility, service), and personal relationships (respect, kindness, generosity, loyalty, veracity). White's main substantive legacy was presented as the stewardship of floodplains, along with effective ways of communicating and institution-building. His paradoxical qualities were framed as optimism and faith in the face of evil.

White (2002) himself identified six periods of his career and four research themes that carried through most of them.

1. Early influences – university, ranching, and Quaker service
2. Periods of development
   a. The New Deal
   b. Vichy's France and Germany
   c. American Friends Service Committee
   d. Haverford College
   e. University of Chicago
   f. University of Colorado

He described his four main scientific and policy interests as: (1) floods and other natural hazards; (2) integrated water management; (3) environmental effects of water management; (4) postaudits; and (5) professional geographers. The key ideas in these works were human adjustment to natural hazards, alternatives in water management, and environmental effects of natural resources management. He pursued these studies, "in a spirit of trying to be helpful to needy fellow humans by cooperative nonviolent methods" (White, 2002: p. 364), and noted that his greatest personal satisfaction lay in observing the contributions of former students. His final comment was that "a basic judgment of geography is what it contributes cooperatively in fashioning a sustainable earth" (White, 2002: p. 364).

After White died in 2006, a series of memorial essays again weighed his contributions, increasingly in terms of ethical and religious values as well as scientific content (Burton, 2008; Kates and Burton, 2008; Murphy, 2008; Palm, 2008; Wescoat, 2006). Kates and Burton (2008) organized one of these essays under the headings of local studies, national comparisons, and global challenges, evoking an important work in White and Hass's (1975) career on natural hazards. The most recent memorial essay published by the National Academy of Sciences by White's long-time protégé and colleague Robert Kates (2011) linked five substantive research fields and associated normative aims:

1. Early emphasis on public water supplies
2. Natural hazard reduction
3. Making peace by managing water

5. Human development and environment

Kates concluded his biographical memoir with a description of the glass artistic memorial by White's daughter Mary in the Boulder Creek floodplain.

Rereading Gilbert White's Contributions to Environmental Geography

This rereading of White's research takes Mary White's artistic memorial to her father as its starting point (http://www.colorado.edu/hazards/gfw/GFW_memorial.html). It stands as a simple individual upright glass column, sited along Boulder Creek near the headgate of an historic irrigation ditch. Its thin pillar of blue-green glass tiles tapers from about a foot in width at its pedestal to several inches in width at its peak. Heights of historic and projected floods are demarcated in the glass, and it has interior lighting that shines through the glass at night. It thus conveys the form as well as philosophy of a creative individual in a social environment. This is an apt perspective for reading White's work.

White's (2002) autobiographical essay conveyed a sense of unity of purpose in geographic inquiry, which he described as 'fashioning a sustainable earth'. His diverse contributions and pluralistic worldview could lead one to interpret his work as wide-ranging, even eclectic, but a stronger argument can be made for the unity of its contributions to what may be termed environmental geography. To say this is to go beyond the twentieth-century hyphenated framings of the man–land, environment–society, nature–society, and human–environment branches of geography, and to suggest that White worked toward a simpler approach that wove together natural resources, natural hazards, and environmental management.

Early Influences and Studies from Chicago to Wyoming

White cited three main formative experiences, first, as a student in John Dewey's Laboratory School and subsequently in the Department of Geography at the University of Chicago; second, in summers working on a family ranch in Wyoming; and third, in his college introduction to Quakerism. All three emphasized the unity of experience within an expanding appreciation of the vast diversity of the world. Dewey (1929, 1934/1958, 1938) likewise focused on environmental experience as the basis for breaking down dualisms between mind and body, nature and culture, and other formalisms in philosophy and education. He regarded organism–environment relationships not so much as a dialectic as a complex process of experimental inquiry striving toward ends-in-view. He wrote that organisms, including human beings, exist not just within but rather as part of and because of their environment (Dewey, 1934/1958).

At that time, during the 1930s, the University of Chicago was one of the early leading geography departments in the US Although Dewey had long since moved to Columbia University, some of his ideas persisted both in education and

in ecological modes of inquiry across the natural and social sciences. White's advisor, Harlan Barrows (1923), published an influential essay on 'Geography as Human Ecology', at a time and place where ecological ideas and methods were widespread in the University. It was a time of interdisciplinary ecological research among botanists, urban sociologists, and landscape architects as well as geographers (Entrikin, 1980).

Ecological modes of social thought concerned White throughout his career. White was a bit late for their flowering in the early twentieth century, and a bit early for their revival in the early twenty-first century, though he would build upon the former and contribute to the latter. Although in some universities in the United States ecological approaches to social issues went into eclipse in mid-century, displaced by other analytical and hermeneutical methods, various strands of urban ecology, cultural ecology, periodically flourished.

White was exposed to Quakerism through a visit by Haverford philosophy professor Rufus Jones to the University of Chicago (pers. comm. *c.*2000). Jones was a mystical Quaker philosopher who became a particularly close personal mentor when White was president of Haverford College in the late 1940s. Jones' conception of experience and being was more akin to the pragmatism of William James' *Varieties of Religious Experience* than that of John Dewey (James, 1902). Indeed, he argued that, "We need to come back from thin behaviorist theories and scant pragmatist conceptions of mind to recover the mind's true amplitude and scope of creative activity" (Jones, 2001: p. 57). Jones' environmentalism linked soul, nature, and cosmos. For example, in writing laced with geographic metaphor, he wrote:

> We do not know how far our own margins of being reach. We cannot completely map the full area that belongs to us. No one can with certainty draw the boundary between himself and the beyond himself, any more than we can tell where the tidal river ends and the ocean begins, but we unmistakably feel on occasions that tides from beyond our own margins sweep into us and refresh us.
> (Jones, 2001: p. 14)

Jones' environmentalism was thus boundless. While White did not write in that mystical mode, he drank it in and sought to live it more in actions than words (White, 2002: p. 364).

Early Contributions to Natural Resources Planning and Policy in Washington, DC

White's first professional experience and writings were not in the academy but rather in government service during the Roosevelt administration. It was not an uncommon career path among geographers at the University of Chicago in the 1930s – some went to the Tennessee Valley Authority and others to various policy and planning centers. With Barrows' recommendation, White was appointed as a temporary assistant first to the Mississippi Valley Committee and then to full time service for New Deal advisory bodies such as the Natural Resources Committee and Natural Resources Planning Board. White's work in Washington concluded with 2 years of policy studies in the Bureau of the Budget.

- Geographer with the Mississippi Valley Committee; National Resources Committee; and National Resources Planning Board, 1934–40
- Staff Member, Bureau of the Budget, Executive Office of the President, 1940–42

In substantive terms, this involved studies of integrated approaches to land, water, flood hazards, and energy resources. White published several scientific papers during the 1930s primarily in water resources and planning journals. Most of his natural resources writing contributed to multidisciplinary committee reports, e.g., river basin surveys, which remain excellent examples of applied scientific writing. Other writings were memoranda for and responses to requests for information from President Roosevelt and others in his administration. These publications followed Harlan Barrows' discipline of succinct issues-driven writing supported by data and judicious weighing of alternative courses of action.

White was increasingly active in Quaker affairs in Washington, so that when the US entered World War II, he left the administration to do relief work in France, but not before finally completing his doctoral dissertation. White's dissertation on *Human Adjustment to Floods* (1942/1945) had an enduring impact on water resources research and has proven to be one of his most influential works (Mcdonald et al., 2012). It began with the paradoxical observation that the more the federal government spent on flood control works the greater the flood losses. It was not simply that flood control had no effect on loss reduction, but rather that it increased the likelihood of increased losses from major flood events. This has subsequently been referred to as the 'levee effect', which encourages floodplain development by increasing perception of flood protection, which is true for high-frequency low-magnitude flood events, but which poses increased physical and economic hazards in the event of levee failure during low-frequency high-magnitude events. With the dissertation completed, White did service as a conscientious objector in France, where he was captured and interred for 19 months in Baden–Baden, Germany, during which time he and others taught and took classes, including Russian, which proved important for his research on US-USSR scientific collaboration during the Cold War era.

Academic Administration and Resumption of Resource Policy Studies at Haverford College

Repatriated in a prisoner exchange in 1944, White returned to Philadelphia for 2 years of humanitarian work with the American Friends Service Committee on Bengal famine relief, voluntary service, peace activism, and other concerns published as pamphlets before and during his presidency at Haverford College, a position he held from 1946 to 1955.

During that period he made several important research contributions. The first was to natural resources studies of the new United Nations, including the first international conference on the subject at Lake Success, New York. International river basin management inspired in part by the Tennessee Valley Authority (TVA) model was one of the main themes at that conference. In an influential review article, White (1957) wrote that while "no two rivers are the same," it is useful to

make broad comparisons of development trends, such as the transition from single- to multipurpose storage reservoirs. He also led integrative studies of arid land management sponsored by UNESCO, at a time of major drought in the US (White, 1956).

Additionally, White resumed his work on US national water policy studies contributing to a presidential commission on *A Water Policy for the American People*, which continues to deserve attention for its recommendations at a time when national water policy has eroded (Christian-Smith and Gleick, 2012; President's Water Policy Commission, 1950). Finally, it was not until this time that be began to publish articles in geography journals, the first of which was, *Toward an Appraisal of World Resources* (White, 1949).

Less well known from this period are White's short essays on issues, trends, and creative approaches to undergraduate college education, including international studies. This combination of voluntary service, national and international natural resources policy, as well as college leadership was heady but difficult to sustain. Prompted by a challenge from anthropologist Margaret Mead that he would not be able to sustain scholarly research, White decided to take his first full time academic position at the University of Chicago's Department of Geography in 1956, at the age of 41, where he remained for 13 years.

Integrating Natural Resources and Natural Hazards Research from the University of Chicago

The 1960s marked the first formal academic research activities of White's career, and they included recommitment to geographic research. One of White's first publications at Chicago was an essay on the department's approach to graduate study in geography, which described early diagnostic appraisals of students and potential advisor–advisee relationships (White, 1958).

Funded collaborative research with doctoral students constituted a new mode of inquiry. In addition to its empirical contributions to knowledge about patterns and processes of floodplain occupancy in the United States, vis-à-vis flood control and flood damage research, these studies addressed sensitive issues of land use planning in water resources research (White et al., 1958, White, 1961a, 1964a). Another innovation involved methods for eliciting and comparing natural hazards perceptions across different social groups, ranging from floodplain occupants to water planners, which were compared with hydrologic risk estimates, as partial explanations for hazards exposure and behavior.

Generalizing from this work, White's theoretical contribution in this period was a sixfold model of natural resource decision-making (White, 1961b). The six key components were: (1) resource assessment; (2) expansion of the range of choice; (3) assessment of technologies; (4) assessment of economic efficiency; (5) spatial linkages; and (6) social guides. While resource assessment was a classical form of geographic inquiry, expanding the range of choice was one of White's most significant transdisciplinary contributions (Wescoat, 1987; Mitchell, 2008). The range-of-choice concept was advanced in part through a pair of National Academy of Sciences studies that White chaired on *Alternatives in Water Management*, and *Water and Choice in the Colorado River Basin: An Example of Alternatives in Water Management* (National Research Council, 1966, 1968).

This framework was subsequently applied to issues ranging from flood hazards and forest management in the US to domestic water supply in East Africa and comparative international river basin planning around the world. The East African study stands out for its enduring classification of water-related diseases by transmission paths, developed by coauthor David Bradley, for its combination of meticulous field research and compassionate reporting authored by Anne U. White, and for its subsequent replication by geographer John Thompson and colleagues in East Africa (Thompson et al., 2001).

In summary, this was a period of theorization and conceptual model development. It diverged from utilitarian and systems analysis models of the time and has subsequently been characterized as advancing a pragmatist logic of inquiry in geography (Wescoat, 1992).

Integrating Resources, Hazards, and Environmental Management at the University of Colorado

White had a lifelong passion for the semiarid western region of the United States, so that moving to the University of Colorado at Boulder was an attractive final career move, in part for its active Quaker community, which included economist Kenneth Boulding who helped recruit White to join the university. White had deep differences at that time with the University of Chicago administration's treatment of student Vietnam War protestors (Hinshaw, 2006: pp. 111–113; White, 1964b).

The University of Colorado presented a final major career challenge that would yield his most significant institutional contributions to the natural hazards field. White was recruited to direct the Institute of Behavioral Science which housed interdisciplinary research groups on environmental and social issues. There he codirected studies such as the first national *Assessment of Research on Natural Hazards* (White and Haas, 1975); edited a volume on *Natural Hazards: Local, National, Global* (1975); and coauthored the volume on *The Environment as Hazard* mentioned earlier in this article (Burton et al., 1978). The 1970s were thus a productive expansion from floodplain research to the broader interdisciplinary field of natural hazards research before White officially retired in 1978. The most influential and lasting institutional accomplishment of this period was establishment of the Natural Hazards Research Applications, and Information Center (or the Natural Hazards Center) as part of the Institute of Behavioral Science. In addition to its clearinghouse function, the Natural Hazards Center convenes an annual summer workshop of several hundred participants to forge long-term relationships between academic and practitioner communities. It established predisaster 'quick response grants' to support immediate research travel to disaster areas to better understand relief phenomena, and it gave special support for doctoral students and young scholars.

White's research would continue for another 25 years, during which time it shifted to a major emphasis on environmental effects of resource use, from the local scale of

Boulder County to early international studies of climate change with the Scientific Committee on Problems of Environment (SCOPE), environmental effects of nuclear war, nuclear waste disposal at the Yucca Mountain site in Nevada, a diagnostic study of the Aral Sea basin crisis, nonpoint source depletion, and other concerns. During the 1980s White served as editor for *Environment* magazine. He was deeply concerned that water and hazards research were not well integrated with environmental inquiry (Wescoat and White, 2003).

Although oversimplifying the continuities in White's career, it is reasonable to note that the 1960s stand out for research on natural resource management, the 1970s for natural hazards, the 1980s for environmental issues, and the 1990s for his essays on the interrelationships among these fields. As noted in his autobiographical essay, he described the role of geography as helping "fashion a sustainable earth," and concluded that "With that aim, the geographic discipline has solid performance, and expanding opportunities." (White, 2002: p. 364). In his final years, White referred most often to his research field as geography and as environmental management. It seems reasonable therefore to join these two terms together as environmental geography.

Legacy: Local, National, and Global

As Gilbert White's many honors and accomplishments are listed on a website dedicated to his work at the University of Colorado at Boulder's Natural Hazards Center, his many medals, honorary degrees, and lifetime achievement awards will not be listed here (see Hinshaw, 2006: pp. 310–313; http://www.colorado.edu/hazards/gfw/). Instead, it may briefly be mentioned that there are fellowships in his name at the Resources for the Future, the University of Colorado; a named chair at Arizona State University; and an annual memorial lecture at the National Academy of Sciences; to name a few. His local influence is marked by the floodplain memorial discussed above, along with a trail named after his wife Anne U. White for her work in Boulder. White mentioned personal satisfaction in his students who themselves have supervised cadres of doctoral students who have become in turn environmental professionals and faculty members primarily in departments of geography (e.g., a couple of third generation examples include Dow and Downing, 2011; Mustafa, 2013; Showalter and Lu, 2010).

In the years following White's death in 2006 through 2012, the Web of Science Citation Index indicates that his work has been cited some 324 times at an increasing rate from 24 to 59 citations per year. Over the longer term, White's most cited works (>100) have been: *The Environment as Hazards* (Burton et al., 1978 – 233 citations); *Drawers of Water* (White et al., 1972 – 157 citations); *Assessment of Research in Natural Hazards* (White and Haas, 1975 – 149 citations); and *Human Adjustment to Floods* (White, 1942/1945 – 140 citations). It is interesting to note that with the exception of his doctoral dissertation, all of these studies were collaborative works. The continuing influence of White's research on water, hazards, and environment, including a dissertation published more than a half-century ago, is unique among twentieth century environmental geographers in the United States and perhaps globally.

White-Collar Workers, History of

M Prinz, Emsdetten, Germany

© 2015 Elsevier Ltd. All rights reserved.
This article is reproduced from the previous edition, volume 24, pp. 16496–16500, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

The category of the 'white-collar' or professional nonindustrial worker has permeated the social sciences since the World War II, although the origins of the term can be found in earlier German thought. White-collar has frequently been opposed to blue-collar or manual/industrial labor, and the distinction has been central to discussions of the nature and likely future of advanced capitalist societies. More recently the usefulness of the term has been questioned, and the class-based nature of social relations opposed by analyses emphasizing the extent to which white- or blue-collar labor reveals little about the social structure and social attitudes.

In most countries the term 'white-collar' worker refers to a group of dependant workers, which compared to manual or 'blue-collar' workers, are occupied not directly in the process of manufacturing. Its delimitation and its specific social profile in relation to blue-collar workers and public servants, however, remain ambiguous and controversial. White-collar workers were introduced into the realm of modern social science at the end of the nineteenth century. The most intensive debates took place in German-speaking countries from about 1890 up to the 1930s against the background of the formation of strong labor movements (largely blue-collar) and in the context of a political system, dominated by conservative elites eager to defend the status quo and in search of numerically important allies among the general population. After World War II the once clear distinction between white- and blue-collar workers were largely blurred and scientific as well as political interest in the group as a whole has faded. It is one chief characteristic of debates in international social science on white-collar workers ever since that they tend to relate only to subgroups as the technical staff ('new worker'), the engineers ('technocracy'), managers ('managerial revolution'), etc. Any wholesale white-collar sociology appears to be a thing of the past.

Preliminary Remarks

Although now in many developed industrial societies white-collar workers represent, at least in numerical terms, the single most important group within the general workforce, their delimitation and their specific social profile in relation to blue-collar workers and public servants remain ambiguous and controversial (Kocka, 1980, 1981; Lockwood, 1989). With hardly any other social stratum was and is the complex interrelation between the actual appearance of a group, its self-definition and its treatment as an object of investigation so clear as with the white-collar employees.

The sociological interest in these groups has a long tradition, which dates back into the late nineteenth century. It arose mainly for two reasons: (1) the exceptional rapid growth of the various groups, labeled as 'white-collar workers,' *Angestellte*, *employŭs*, *impiegati*, *empregados*, etc., and (2) the fact that these groups, with regard to some objective features of their working conditions, aspects of their legal status, as well as their consciousness and their behavior, differed markedly from other social groups already established. Interest was nowhere so strong as in the German-speaking countries, where, as a field of the emerging social sciences, a special *Angestelltensoziologie* developed. This peculiarity was mainly due to the existence of a radical labor movement and of a strong bureaucratic tradition. The institution of the privileged 'civil servant' served as a role model for many white-collar workers and attributed much to the relative depth of the distinction in relation to the blue-collar workers in the respective countries. However, comparative historical research shows that the terms 'white-collar workers,' *Angestellte*, *employŭs*, *impiegati*, and *empregados* are in no way interchangeable. The delimitation and, particularly, its social 'meaning' vary strongly historically and from country to country. Though much of the special social profile of the various groups labeled as 'white-collar' has faded away, there still remain some important differences, especially in relation to blue-collar workers.

Definition by Functional Criteria

In many countries in everyday language as well as in scientific usage the term white-collar worker refers to a group of dependent workers, which compared to manual or blue-collar workers, is occupied not directly in the process of manufacturing. Rather it is situated in functional as well as in spatial terms *before* the process of manufacture, *beside* it and *behind* it. One encounters white-collar workers in all economic sectors, even agriculture, at least, as it is organized commercially and as a large-scale business. However, the actual domain of the employees is the service sector that is, trade, banking, insurances, where they always made up the predominant part of the workforce. In addition, large groups of employees are to be found in industry and the public sector. Since the end of the nineteenth and above all in the course of the twentieth century employees have increased their share in all sectors considerably in all developed societies compared to that of manual workers and public servants (**Table 1**).

Table 1 White-collar workers in US, Great Britain, and Germany 1882–1950 (in percent of the total labor force)

	USA	*Great Britain*	*Germany*
1882			6.1
1900	12		8.5 [1895]
1910	15	18.7	11.7 [1907]
1921	19 [1920]	21.2	16.0 [1925]
1931	22 [1930]		17.1 [1933]
1939	24 [1940]		18.9
1950	30.9	30.9 [1951]	19.9
1970			35.7
1987			50.1

Source: Behringer, P., 1985. Soziologie und Sozialgeschichte der Privatangestellten in Großbritannien. Frankfurt, Germany, p. 515; Kocka, J. 1980. White-collar Workers in America: 1890–1940: A Social-political History in International Perspective. Sage, London, p. 42f; Kunig, p. 172. Note: These numbers include white-collar employees in private businesses as well as in the public sector.

With respect to their productive functions white-collar workers differ from manual workers in that they – varying with the economic sector in which they are employed – perform directing, overseeing, constructive, analyzing, administrative, commercial, and information-processing tasks. These criteria may lead, in many cases, to a clear distinction between manual workers and white-collar employees in private enterprises. They are hardly suitable for a clear distinction between officials or civil servants (*Beamte*) and employees (*Angestellte*) in the public sector. The functions of these two categories normally overlap. But the upper ranks of the hierarchy are staffed by employees with the status of civil servant (Humphreys, 1958). *Beamte* and *Angestellte* differ by legal status rather than by types of functions.

Origin and Growth

The origins of some white-collar professions may be traced back to the premodern period. Among them figure, for instance, the commercial employees, which at that time still had a good chance to reach the status of a self-employed salesman later in life. Nevertheless as a mass stratum one has called white-collar employees rightly the 'latest child of industrial capitalism.' Two main developments contributed to the rapid growth of the group: (1) the shifting balance between the 'first' (agriculture) and the 'second sector' (industry) in favor of the 'third,' the service sector (Fourastiй, 1963) – a development that took place first in the Great Britain while other industrial nations followed suit in the course of the nineteenth and twentieth century; (2) the rise of 'Organized Capitalism' (Hilferding, 1981) since the end of the nineteenth century, a phase characterized by the growing importance of organization, planning, information-gathering, bureaucratic control, and the creation of structures within and outside industry to serve these ends. The relative growth of the share of the employees within the public sector, however, is determined not only by changes in the function of the modern state but also to a large extent by the political will either to expand or to restrict the spread of particular privileges attached to the status of civil servant (*Beamte*). Such privileges are, for example, the protection against dismissal and pension schemes, etc.

As recent social data show, even in the most advanced contemporary industrial societies the expansion of white-collar jobs has not yet come to an end. But there are clear signs that the rate of expansion slowed down significantly in the second half of the twentieth century. As with all social growth, the creation of white-collar jobs as a strategy to tackle problems arising from the development of economy and society as a whole is subject to the law of diminishing returns. While in the early stages of industrial capitalism white-collar employees were instrumental in the process of rationalizing production – a fact that caused widespread resentment among manual workers – in further stages they were themselves subjected to strategies of cost-cutting and rationalizing. This development began very soon after the turn of the twentieth century with the introduction of specific office machines as the typewriter, the Hollerith machine – an early form of large-scale data processing – and other changes in the structure and organization of office work. This process definitely has gained a new quality in recent years. In particular, the spreading of the computer, the communication revolution, and the integration of office work into controllable networks has opened new chances for quantitative control of employee activities once considered to be typical only for manual work. Whether this tendency is outweighed by other trends toward 'lean management' and more autonomy on the job remains to be seen.

Status and Privilege

The Swedish–German sociologist Croner (Croner, 1951) developed his 'theory of delegation,' according to which, most early white-collar jobs in industry emanated through a process of division of labor and of delegation out of functions originally performed by the employer. This theory has been questioned by empirical research. Especially in modern industries many tasks performed by white-collar workers actually represent new functions without any historical precedent. It seems highly questionable that *all* early functions classified as white-collar carried with them high prestige. Especially, in the area of small-scale shop keeping there existed extremely exploitive working conditions for clerks with low pay, no job security, long working hours, etc. (Anderson, 1976; Crossick, 1977). Nevertheless, it holds true that many white-collar occupations enjoyed at least some form of privilege in comparison with manual workers, and continue to do so. Some of the differences resulted from the specific nature of their work that could not be subjected easily to quantitative methods of control. One of the traits that distinguished most – not all – white-collar jobs from blue-collar functions was a fixed income, the 'salary,' that, at least in principle, did not vary with working hours or the amount of work carried out. Because of the fact that knowledge of business transactions within the specific firm constituted the main qualification of many white-collar employees, the accumulation of such individualized knowledge gave members of the group a higher job security

than manual workers, especially in the early stages of industrialization. Even in later days, the office never became the place for a general 'hire and fire' climate. As many positions of white-collar workers were integrated into large, delicately differentiated bureaucratic hierarchies, aspirations for upward mobility never vanished completely. Besides, in many countries there were, traditionally, legal privileges attached to certain white-collar occupations. These entitlements included protection against dismissal, paid vacation, continuation of wage payment in the case of illness, company pensions schemes, etc.

The idea that the class of white-collar workers as a whole would face 'proletarianization,' as put forward especially by writers in the Marxist tradition, has given way to a much more nuanced picture. At earlier stages of the development legal privileges attached to certain types of white-collar workers were generalized among larger groups. Moreover, the French sociologist Michel Crozier has argued that the consequences of rapid rationalization were often absorbed by the constant influx of female workers. Though the equation 'proletarianization-feminization' does not come out, there is some degree of truth in it. New styles of management – the movement toward 'lean management' since the 1980s, for instance – have amplified autonomy and reopened scope, at least, for certain groups among the white-collar population. On the other hand, there can be no doubt that a process of narrowing and even blurring of differences between blue-collar and white-collar workers took place in the course of the twentieth century. Important groups within the white-collar population, especially clerical workers and sales personnel, have been overtaken by skilled manual workers in terms of income, job security, even prestige. Many of the rights once attached exclusively to certain white-collar positions have, step-by-step, been granted to the workforce as a whole, making white-collar workers, at least in some countries such as Germany, important, if involuntary, harbingers of the modern social state. Though, on average, white-collar workers still appear to be privileged in relation to the manual workforce, the 'average' white-collar worker largely has become a statistical fiction due to the immense variety of positions and professions that nowadays characterize these categories.

Organizational Behavior

Depending on the structure of the trade union movement within the respective countries, white-collar workers tend to organize exclusively or are integrated into general unions (Behringer, 1985; Bain and Pollins, 1965; Bain, 1972; Jenkins and Sherman, 1979). In most cases union membership among white- and blue-collar workers overlaps at least to a certain degree. The main area in which both groups differ is trade union membership in general. White-collar workers are considerably less well organized than manual workers with the one exception of the public sector. Hence, their growing weight among the workforce represents one of the most important factors in the crisis of the trade union movement in developed countries in general.

National Differences and Peculiarities

While in most industrialized countries the division between white- and blue-collar workers was never clearly marked or valid only in regard of relatively small groups, in some European countries such as Austria, Czechoslovakia, Switzerland, and Germany until the middle of the twentieth century, blue- and white-collar workers constituted distinguished entities, separated in many aspects, legal as well as organizational and ideological. Social legislation, especially pensions schemes, had been enacted before and after the World War I. They had an important impact, strengthening existing differences between white- and blue-collar workers. The dividing line between the two groups structured large parts of the fabric of these societies – legislation, trade union movement, self-help organizations, political affiliations, etc. By the 1950s, the distinction between white- and blue-collar had begun to erode gradually, a development that was supported by the expansion of former white-collar privileges to the general workforce. Another important aspect in which German-speaking countries before the World War II differed from other societies was the sheer size of the legally defined white-collar population, which included sales personnel as well as general managers.

Social Theory

White-collar workers were introduced into the realm of modern social science at the end of the nineteenth century. The starting point was twofold: (1) the notion of a growing number of occupations, employments, and functions that shared many traits of the working class while at the same time differing in important aspects from manual workers as well as from the higher social strata; and (2) the exceptional rapid growth of these categories in the decades around the turn of the century, which even outdid that of the manual workers.

The most intensive debates on white-collar workers took place in German-speaking countries from about 1890 up to the 1930s against the background of the formation of strong labor movements (largely blue-collar) and of a political system, dominated by conservative elites eager to defend the status quo and in search of numerically important allies among the general population. In the first stage of the debate, which took place before the World War I, status quo-oriented scholars identified white-collar workers as part of a new socially stable and conservative 'middle estate' and, at the same time, encouraged the state to engage in a social-protective policy (e.g., white-collar specific insurances and labor laws) while Marxist theorists predicted a general proletarianization of these groups. The 1920s saw a convergence of opinions, reinforced by the skeptical notion that the 'new middle class' in German-speaking countries seemed to figure prominently among the mass base of National Socialism. The label of a potential for right-wing extremism has stuck to the group ever since, not least through the intellectual influence of German social scientists, many of whom were forced to emigrate in the early 1930s (Fromm, 1984; Speier, 1986). The notion showed up again

in many theories of fascism developed in the 1950s and 1960s, generalizing what was seen to be the experience of the interwar years (Lipset, 1960). In contrast, social historians who took up the debate in the 1970s tried to demonstrate the peculiarities of the German and Austrian experience (e.g., Kocka, 1980) while latest research has challenged the notion of a predominantly right-leaning, 'new middle class' in the 1920s altogether (Falter, 1991).

The debate over the role of white-collar workers in the mass base of National Socialism represented the climax and at the same time a turning point. Interest in interpretations of the white-collar group as a whole has subsided (but see Schulz, 2000) in Germany as well as in other countries where it never figured prominently.

Not surprisingly, with regard to the heterogeneity of the group, social science attributed contradictory attitudes and social functions to these groups, often departing from specific traits of subgroups. One important theme over the decades has been the impact the expansion of white-collar occupations has had on the emancipation of women, whether it offered new opportunities for social mobility or whether it only helped to reproduce traditional inequalities (Suhr, 1930). There has been much research on the impact of rapid technological change on office work through the decades, some with more pessimistic, others with more optimistic overtones. Studies of the service sector, for instance, stress its relative resistance to change as a result of the need to maintain a workforce even when there is no constant demand, a fact, which has been labeled 'guard labor.' Other scholars have pointed to the partial regain of autonomy on the workplace as part of the automation movement in the 1970s, which was said to have led to the formation of a 'new worker' (Mallet, 1963). Actually, the debate referred to members of the technical staff supposedly holding key positions for potential labor disputes. Another important context was the rise of modern consumer society since the World War I in Europe and the United States. The concentration of large numbers of white-collar employees in larger cities led to the identification of them with the urban population as a whole, regarding them as pioneers of modern consumption and new forms of leisure (Coyner, 1977). This notion dates back to the influential study first published in 1924, of the German social writer, Siegfried Kracauer (Kracauer, 1998) and translated into many languages ever since. It has been taken up in various studies of the historic development of modern consumption and leisure, leaving out, with regard to the white-collar population, those members of the group living in smaller and middle-size cities.

Though, in the second half of the twentieth century, interest for white-collar employees in the social sciences has flared up from time to time, there seems to be no future for any revival of a wholesale white-collar worker sociology as it developed in some European countries during the interwar years. One of the most important prerequisites, the existence of a self-conscious socialist working class, no longer exists. With its disappearance the interests of social science, policy makers, and the different groups that make up this strata to develop a broad definition based upon the distinction between 'us,' the 'white-collar,' and 'them,' the 'blue-collar workers,' seem to have vanished. What remains is a remarkable gap between the numerical importance of the group in question and its relative neglect by social scientists in the last decades.

Whiteness and White Supremacy

June Ying Yee, School of Social Work, Ryerson University, Toronto, ON, Canada

Abstract

The profession and practice of social work is steeped in whiteness and white supremacy. Whiteness can be viewed as the normalization of helping those who are marginalized via a set of practices and techniques that, in the end, work to maintain the status quo of failing to recognize systemic and structural inequalities that privilege white people. A review of how the social work profession, primarily in North America and around the world, has been shaped by the historical and global evolvement of whiteness and supremacy is considered.

Introduction

Historically, social work practice in North America evolved from two different movements: the Settlement House and Charity Organization Society (COS). The COS started in 1869 in England. In 1877, the United States promoted scientific philanthropy, which emphasized the need to rehabilitate poor people through individual case work (Lundy, 2004). Mary Richmond's first book, titled *Friendly Visiting among the Poor*, provided a manual on how to promote individual change among poor people in an advancing and growing industrial society. At the same time, Jane Addams (1860–1935) promoted social change through the establishment of settlement houses. Addams believed that the state should help poor people, whereas Richmond argued that those who were more fortunate could provide charity work and help for poor people. The approaches of each of these movements signaled a difference in their understanding of how to work with those who are marginalized in society, with the former providing a more individual level focus and the latter providing a social justice emphasis. Nonetheless, both the COS movement and Settlement House practices of intervention were aligned with the dominant values of society, that is, whiteness (Bradley, 2009; Dominelli, 2010; Lundy, 2004; Smith, 1999; Thobani, 2007).

Whiteness can be viewed as the normalization of helping those who are marginalized via a set of practices and techniques that, in the end, maintains the status quo of privileging white people and failing to recognize systemic and structural inequalities. More recent scholarship in social work (Todd, 2011) examines the performative acts of whiteness that simultaneously positions white social workers into a place of 'goodness' with good intentions, while also imposing techniques and practices onto clients that may not be very helpful, if not harmful. From an anticolonial perspective, an understanding of whiteness has helped to shed light on the harmful colonial practices inflicted on particular marginalized communities such as black and Aboriginal peoples. For example, the child welfare system in North America has an overrepresentation of black children and Aboriginal children in care (Chand, 2000; D'Souza, 1994; Delfabbro et al., 2010; Dettlaff and Rycraft, 2008; Trocmé et al., 2004). Questions are being asked about the role and relationship between whiteness, colonialism, and structural inequalities in creating such outcomes.

The recent social work literature (Baines, 2011) has emphasized how social inequalities experienced by service users are often transformed into social problems that social workers are expected to treat as technical problems to problem-solve and fix. In doing so, social control of marginalized people takes place while simultaneously concealing the social inequalities that arise from gender, race, and class inequalities. For example, the use of risk assessment models on clients in the Canadian child welfare system (Krane and Davies, 2000) has been viewed as a technical instrument used to gain social control over service users. Krane and Davies (2000) make a compelling argument that risk assessment models are set up to show the 'dangerousness' of clients' behaviors from the perspective of the dominant group. The consequence is that families are not well-supported or helped at the structural level and, more significantly, marginalized people are put under more scrutiny by public officials and the welfare state than those who hold privilege and power in society (Aronson and Smith, 2011; Baines, 2011, Dumbrill, 2010). This article discusses the role of whiteness and white supremacy in shaping not only the professional identity of social work but also the practice of social work. The article starts with an in-depth and detailed discussion of what is whiteness and white supremacy, and how our understandings of whiteness has shifted and changed over time.

What Is Whiteness?

In North America, the concept of whiteness is a fluid, dynamic, and situationally specific social and cultural process that positions those who are white, in terms of skin color, into a place of power and privilege. Conversely, those who are black, in terms of skin color, are positionally located into a place of powerlessness, marginalization, and oppression. Differential treatment can result in other markers that exclude such as religion, language, gender. However, in this context, whiteness primarily focuses on race as the entry point through which to understand exclusion. The operation of whiteness is complex because the white race is mediated by other forms of identity such as class, gender, disability, and sexuality. Within one's identity, a person can have sites of privilege and oppression operating at the same time (Carniol, 2005; Styhre and Eriksson-Zetterquist, 2008; Yee and Wagner, 2013). Due

to this complexity, such forms of intersecting identities can cause a person who is white not to recognize the power of whiteness within his/her own identity and, instead, to turn to places of innocence and shame. This examination of emotions, known as affective economies, is a burgeoning area in whiteness studies and is paramount to showing why whiteness is a difficult topic to discuss (Ahmed, 2012; Harding and Pribram, 2004; Hunter, 2010). This place of innocence is known as the crisis of whiteness (Bonnett, 2000; Todd, 2011; Wagner, 2010). To date, in the Western world, white people have not been able to reconcile nor confront the historical and present-day enactments of racism that are routinely inflicted upon Aboriginal peoples and people of color. For example, although antiracism is known to be a social movement working toward the dismantlement of institutional systems that benefit white people, we still see the repositioning of white antiracism activists as the 'good whites' (Todd, 2011; Wagner, 2010). Or, another example is how many white feminists, although aware of the way oppression works across gender, may still have difficulty recognizing and discussing their own white privilege while discussing very clearly the dynamics of gender inequality (Lorde and Rich, 1981; Todd, 2011; Wagner, 2010).

Around the Western world, power and privilege is given to those who hold a white racial identity. Even though the definition of white, as a racial identity, is socially constructed, past and present-day political, social, and economic arrangements reaffirm the power of the white race. It is no accident that many examples exist of the differential and negative treatment of those who are nonwhite and Aboriginal. This process of differential treatment is known as racialization. Behind all processes of racialization rests the ability of those who hold power through the white race to grant power or take away power from people. In the Western world, the white race has garnered power through acts of colonialism that are ultimately rooted in notions of superiority and used to justify the economic exploitation of those who are nonwhite. The legacy of colonialism inflicted upon Aboriginal peoples and people of color continues into present day institutional systems and structures without people being aware of it happening. The way it manifests is not always readily apparent or detectable. This is because the enactment of racism itself has been routinized, and naturalized through the strategies and processes of whiteness. Whiteness predates the modern era and Kincheloe (1999) suggests that whiteness arose in Western European societies, during the Enlightenment period, with the construction of a white male rational subject who was able to transcend time, space, and history. Power and privilege is granted to white males through three social and cultural processes (Gabriel, 1998: p. 13): (1) exnomination, that is, the ability to shape the norms and values of everyday life and a failure to ethnicize one's own self; (2) naturalization, that is, seeing the representation and embodiment of white culture as the referential social norm without having to ever define one's own self; and (3) universalization, that is, taking for granted that the worldview of white people is the way to understand everything through its own historical and sociopolitical vantage point. These three social and cultural processes are the strategies and processes of whiteness.

A common theme emerges, which is the invisibility and normalization of social inequality taking place throughout the Western world. If society fails to see the processes of racialization occurring, then those in positions of power and dominance are able to continue to prevail with impunity. This practice of failing to see or notice social inequality is worldwide, but can be applied and transferred to different contexts. For example, although Green et al. (2007) discuss the operation of whiteness in South Africa, they make the insightful comment that "white people [are able] to distance themselves from racism and racial privilege through a range of discourse and practices, which also [simultaneously] protects and secures the dominance and normativeness of whiteness." The ultimate effect is that white people are not required to deal with the realities of white supremacy, which is at the root of the social and cultural process of whiteness (Schick, 2012). According to Schick (2012: p. 13), white supremacy can be defined as

> reasserting white space is a performative act that accomplishes white supremacy and white identity; it also demonstrates and confirms the white racial knowledge of how to do this. "White racial knowledge limits and defines what whites are prepared to hear about a subordinate group and still 'allow a self-concept of innocence to continue' Nelson, 2002: p. 224."

Specifically, in the United States in the 1990s, a proliferation of scholarly studies on whiteness studies increased the consciousness of Americans to the insidious ways in which power and dominance continues to exclude black people from equal participation in society. To illustrate this in the United States, the phenomenon of 'white flight' takes place when a large number of white people leave a racially mixed neighborhood to a more racially white neighborhood due to an irrational fear and anxiety of black people. This fear and anxiety is fueled by the material reality of a legacy of slavery, which effectively denigrated and dehumanized black people. Such a historical past set a material foundation for creating present-day stereotypical assumptions about black people's ability, merit, and worth in the economic labor market. Therefore, in the United States, the economic value of white privilege is dependent on the continued denigration and exclusion of great number of blacks in the United States from the paid labor market even after the abolition of slavery (Baldwin, 2012). This pattern of segregation results in white people benefitting from better chances in obtaining a job, higher wages, capital, and job mobility. Another example is the normalization of white segregated neighborhoods that came through real estate developments that independently incorporated the upkeep and maintenance of such neighborhoods (Baldwin, 2012). This privatization of payment of services effectively allowed people living in these economically exclusive neighborhoods to no longer contribute to general municipal services. The recipients of general municipal services are often associated with low-income neighborhoods, where a lot of nonwhite people may live. This racial divide in the spatial environment of neighborhoods, therefore, not only reflects a fear of blacks but also bolsters the economic value of whiteness (Baldwin, 2012). As evidenced by this example, new forms of colonization are being recreated under the guise of capitalism, merit, and entitlement to private property. In the Western world, capitalism is cherished as a system of fairness, equality, and opportunity but

in reality benefits mainly white people and hides the unequal power relations. Ultimately, this way of knowing the world is created and recreated through the mobilization of strategies and processes of whiteness that are historically undergirded by white supremacy. In the next section, a more detailed discussion on white supremacy is provided.

What Is White Supremacy?

The roots of white supremacy begin with the European white colonizers gaining power and control over the economic, political, and social institutions of the world. The global impact of racial colonialism and justification of capitalist systems to exploit, marginalize, and colonialize people of color and Indigenous peoples are taken for granted as an invisible norm that hardly anyone examines for its current day consequences. One could argue, therefore, that the rise of the modern era of capitalism and past colonial expansion across the globe has secured the dominance and power of the white race with the consequent negative suppression, erasure, and decimation of the lifeworlds of Aboriginal peoples and people of color. Rabaka (2007: p. 8) draws comparisons between the past and present by noting that, in the past, white supremacy enabled whites to use 'racial colonialism and colonial capitalism' to rob Aboriginal peoples and people of color of their autonomous knowledge base while, in the present, we see how 'white hegemonic views and values, white conquest, and racialization colonization' are a reward to whites as evidenced by the inordinate amount of power and privilege granted to them (Allen, 2001; Gordon, 1997; Thobani, 2007).

Therefore, it is important to ensure that any analysis of whiteness moves beyond understanding white supremacy as just the inherent belief in the biological superiority of white people. It is a misnomer to understand white supremacy as only about the extreme hate groups, such as the Klu Klux Klan in the United States. Rabaka (2007: p. 3) argues that white supremacy is "not simply a global and social phenomenon, but a personal and political one as well" that intricately combines three interpretations at the same time: (1) Often race is essentialized into binary understandings of black and white with the result of creating valuations that mislead most to conflate race with culture. For example, Green et al. (2007: p. 397) note that "in colonial contexts, whiteness was represented by orderliness, rationality and self-control, while non-whites were represented by chaos, irrationality, violence, and a lack of self-control" (Kincheloe and Steinberg, 1998); (2) The Marxist analysis of racial inequality, which argues, from a political economy viewpoint, that the 'other' was marginalized for profit and gain of the capitalist system; and (3) Race as a social construction emerged in the modernist era due to Europe's desire for global dominance. This colonial expansion coincided with the rise of science and the Enlightenment period of the white, male rational subject. Regardless of which perspective one favors the resultant outcome is the need to recognize the contemporary reproduction of white supremacist values and practices in the profession of social work. Social work practice operates in the context of processes of whiteness, racism, and colonialism. Therefore, it is important to discuss the evolution of whiteness over time in society before one can begin to understand the ways in which social work practice is entrenched with the social and cultural process of whiteness and white supremacy.

Three Waves to the Study of Whiteness

Whiteness studies (Delgado and Stefancic, 1997; Fine, 1997; Frankenberg, 1997), also known as critical white studies, have crossed into several transdisciplinary boundaries, including ethnic studies, cultural studies, and critical geography. According to Twine and Gallagher (2007), three waves of whiteness studies can be delineated in the scholarly literature: (1) the works of W.E.B. Dubois and other US black scholars; (2) the works of critical legal theorists, feminist theorists, and black theorists; and (3) the development of empirical research using various research methodologies that delve into the operations of whiteness in different contexts whether it be through personal narratives or critiques of current institutional practices.

It is important to note that the ideas that form our current understandings of the white race, and its ideological formations, were central to the scholarly writings of US black scholars for over a century (Twine and Gallagher, 2007) and form the first wave of whiteness. Twine and Gallagher (2007) note that W.E.B. Dubois made three central observations about race and whiteness that lay the theoretical foundation for critical whiteness studies. First, because white laborers from southern and eastern Europe in the Black Reconstruction period in America (1860–80) embraced the identity of the white race, rather than forge a solidarity with freed slaves, these white laborers were able to acquire social and material advantages that only further buttressed the creation of the power of the white racial identity. In other words, white workers were able to gain admission to the social and material privileges of the class that formed the dominant group via a white racial identity, rather than seeing themselves as marginalized like black workers. Although these white workers received a low wage for their labor, they were seen as holding better social status and opportunities than blacks. These white workers who were previously seen as unambiguously white were now seen as part of the privileged white race. Most whites are not consciously aware of their own racial prejudice and such unawareness helps to support white supremacy. W.E.B. Dubois argues that white supremacy is premised on the failure of whites to see that institutional racism exists, despite overwhelming data that shows the racial inequality of blacks. Second, given this historical foundation of not recognizing the discrimination and differential treatment experienced by blacks, at a structural level, W.E.B. Dubois continues his argument by noting that threats to the nationalism of the country, or rather white culture, are coming from the poor culture of blacks. These cultural deficit arguments deflect attention away from the center of white dominance and, in particular, fail to notice or scrutinize its operations of power. Therefore, instead of scrutinizing the source of power, more attention is paid to the marginality and threat of blacks to the economic stability of the US economy. Thirdly, W.E.B. Dubois recognized that this problem of racism toward blacks otherwise known as the 'color line' extended beyond the US border and was a worldwide, international phenomenon.

The second wave of whiteness studies builds on the previous work of US black scholars by challenging the works of mainstream sociologists writing in the area of race. They include the works of feminist scholars, black critical legal theorists, and black theorists. They criticized race scholarship in the United States by noting how white scholars dominated the thinking and approaches of race theory, which were limited to understanding racism as an individual psychological problem, rather than a systemic one. One example of viewing racism primarily at the individual level is through the work of Myrdal (1944). Although Myrdal (1944) did examine the widespread racism that affected every aspect of US society as well as the many Americans' strong belief that equal opportunity is available to all regardless of race, Myrdal (1944) did not go far enough in recognizing that white Americans, did indeed, receive material and economic rewards due to the racial inequality of blacks. But, more importantly, Myrdal (1944) also failed to see the significance of how deeply embedded white supremacy organized America's entire institutional arrangements to the point that people were in denial of this possibility. Consequently, structural interpretations on race were not explored until the second wave of whiteness studies.

Therefore, the goal of the second-wave whiteness writers was to show the invisibility of the white race as the taken-for-granted referential norm that operates not only in US institutions and systems, such as in the courts, but also in the everyday popular discourse and culture of society. For example, Morrison (1922) criticized literary works for defining and equating the word 'American' as synonymously meaning 'white' while all other races were marked as different and less than. Furthermore, Twine and Gallagher (2007) note how the solidification of white supremacy is exemplified in the different historical analysis of various authors' works (Allen, 1994; Jacobsen, 1998; Roediger, 1991). These show how those who are ambiguously white were able to align themselves with the workings of whiteness and, in turn, reap the benefits of white privilege.

Currently, researchers and scholars are in the third wave of whiteness studies. The emphasis of the third wave of whiteness is to examine how people learn and unlearn whiteness along with the complex and different ways in which whiteness can be deployed as a performative strategy whereby those who are white are able to retreat into a place of innocence and non-culpability with acts of racism (Ahmed, 2012; Warren, 1999; Arai and Kivel, 2009). In particular, researchers are interested in using self-reflexivity as a way to understand how whiteness operates in how researchers come to know things and inevitably look at how the workings of whiteness are made invisible in research methods and institutional practices. This is challenging to do since even antiracist authors inevitably reproduce their own power relations while attempting to undo whiteness. In particular, greater insight is also provided on the ways in which white supremacy is undergirding much of antiracism work. Berg (2012) provides four examples of how feminist critical race studies (Thompson, 2003; Wiegman, 1999) reproduce white supremacy while attempting to undo whiteness. First, when white scholars write about whiteness, they run the risk of appropriating the earlier works of scholars of color and Aboriginal peoples and, as a consequence, those who read their work will see them in a favored light, whereas for people of color (Srivastava, 2005; Fellows and Razack, 1998) who speak about the same issues experience violence, harm, and negative consequences to their own personal selves. This difference and impact is hardly discussed in the literature. Second, liberal white people who adopt color-blind approaches to race do not always see how they, too, benefit from an overall system that is stepped in white supremacy and are adept at disassociating themselves from the extremist forms of racism. And, third, even when white feminists or profeminists pursue an antiracist identity, they inevitably recenter themselves, in the process, by claiming a position of innocence. In claiming innocence, these white antiracist activists ignore their own complicity in the reproduction of white supremacy. The literature (Schick, 2012; Todd, 2011) being developed in this area is known to be tackling the problematic of whiteness.

Although earlier scholarship on whiteness was primarily focused in the United States, more recent scholarship is exploring the impact of the dominance of European powers as producing Eurocentric thought not only in international contexts, but also in local contexts. Certainly, European colonization in South Africa, South America, Africa, Australia, New Zealand, North America, and the Caribbean has greatly influenced the global and economic order of the world. Still forthcoming is more research and scholarship that puts forth a global and comparative analysis on the workings of the ways in which whiteness and white supremacy operate together (Allen, 2001; Bhattacharyya et al., 2002).

Professional Identity of Social Work Steeped in Whiteness and White Supremacy

Historically, the social work profession struggled to create a unique professional identity of its own that carried legitimacy and merit in comparison to other professions, such as the medical profession. Flexner, a well-known and recognized expert on professional schools, remarked that social work did not seem to be a profession because of its failure to demonstrate a specific knowledge base with unique activities and techniques of its own with specialized professional expertise. For example, social workers were seen as helpers, but not as expert professionals. To gain legitimacy as a profession, Richmond published the book *Social Diagnosis* based primarily on the medical profession's scientific approach of diagnosing, and treating a client's presumed individual pathology. This approach to social work was in alignment with the already preexisting value base of the COS, which includes principles of administration and efficient organization, a central feature of scientific philanthropy. It is thus, no accident, that the setup of social service organizations, today, is primarily based on this model of organizational practice on how to serve clients. Examples of social service agencies that follow this task-centered model approach to practice include child welfare and family service agencies, boy and girls clubs, counseling agencies, and drop-in centers.

As discussed earlier, the scientific model is a part of the Enlightenment movement that places enormous value on the white, male rational subject who garners power and dominance in the creation of knowledge about the 'other.' However, most social workers are unaware of the predominance of this

colonialist and imperialist underpinning of the social work profession because of the effective deployment of strategies and processes of whiteness that operate in everyday social work practice (Yee and Dumbrill, 2003; Yee, 2005). More importantly, this overemphasis on individual counseling and use of the scientific model has caused social workers to shift away from studying the social conditions and systemic causes of people's marginalization in society. In fact, Lundy (2004) argues that psychodynamic theory dominated social work practice from the 1920s through to the 1960s. This history of whiteness, in the context of global imperialism, has white women leading the way in this work. Roger (2000) has argued that although psychotherapy was a form of resistance by white women to male patriarchy, this therapeutic approach still reinforced the regulation of all women and, worse, regulated people of color and Aboriginal peoples. In response, feminism, antiracism, and Aboriginal worldview perspectives have attempted to expose the hidden and not-so-evident forms of male patriarchy, racism, and colonialist acts that are play out within institutional practices.

White women, in particular, played an important role in this historical development of the social work profession. During the time of the COS movement, white middle-class women out of empathy wanted to help the 'deserving poor.' Their understanding of the plight of the marginalized has been critiqued as coming from a place of middle-class moralizing. Many of these bourgeois white women were also Christian missionaries who have been labeled by critical white studies scholars as do-gooders who wanted to help (Roger, 2000). Psychotherapeutic practice with people of color and Indigenous peoples could not adequately deal with issues of racism and colonialism and carried its own built-in whiteness. For example, why is it that child welfare frontline practice is dominated by new graduates who are young, white females (Fallon et al., 2003; Pon et al., 2011)? In doing so, we see the ways in which whiteness is secured in these hiring practices. Power granted to white females effectively positions them as the "'knowers' of the helping profession" (Roger, 2000: p. 138). Over time, white women will possess an investment in this type of practice making it much more difficult for them to undo their own whiteness. This contradictory stance and tension resides in the psyches and practices of white women.

Given these critiques about whiteness and white supremacy in the social work profession, more recent scholarship has also examined the possibility of exploring a post-race society. A post-racial society is one where people's experiences do not match their racial identity (Steyn and Conway, 2010). In other words, to essentialize race, including the racialization of white people, restrictively takes away from the ways in which strategies and processes of whiteness are fluid, malleable, and mobile. That various groups of people can benefit from whiteness and, in turn, bolster and support white supremacy shows the complexity of how power and dominance operates in a global world. For example, Shaw's (2006) work is aimed at decolonizing whiteness. Too often, whiteness studies are focused solely on 'white' ethnicity with an Anglo focus. Ironically, such metanarratives about white dominance may inadvertently recenter whiteness. As noted by Shaw (2006: p. 865), "whiteness is a process that not only racialised and excludes, but de-ethnicizes and *includes* otherwise ethnicized group, as required." Similarly, Twine and Gallagher (2007) argue that for us to understand the operation of whiteness, there needs to be more research done on the ways in which ethnic minorities are co-opted into strategies of whiteness that in the end, maintain white supremacy.

Conclusion

If we apply research and scholarship on how to end white supremacy, there may still be possibilities on how to create real change to the profession of social work. This requires, though, a deeper and theoretical understanding of the ways in which whiteness and supremacy undergirds the social work profession. Rabaka (2007) argues that white supremacy will not end until we allow for knowledge making that comes from people of color and Aboriginal peoples to inform the values of what is needed in social work. In doing so, this is not about culture, but about actual life worldviews that teaches everyone about alternative systems that are outside of a colonizing and white supremacist viewpoint. Currently, in the social work profession, more research is emerging about the importance of allowing the service users voice to be heard. Whether service users will be allowed to garner institutional power that actually changes the values and norms of the organization is yet to be seen. Because service users come from a diverse set of backgrounds along the sites of race, gender, class, and disability, we may yet be able to bring in fresh perspectives that challenge the status quo of whiteness and white supremacy in the profession of social work.

Whorf, Benjamin Lee (1897–1941)

Joseph L Subbiondo, California Institute of Integral Studies, San Francisco, CA, USA

Abstract

Benjamin Lee Whorf (1897–1941) advanced a theory of linguistic relativity in which he maintained that one's language substantially affected one's worldview. His 'principle of linguistic relativity,' as he referred to it, has often been identified as the Sapir–Whorf Hypothesis because Edward Sapir (1884–1939) inspired Whorf's development of the concept. In addition to his version of linguistic relativity, Whorf introduced the allophone that enhanced the study of phonology and he formulated covert grammatical categories, which explained the role of grammar in modeling reality. In his initiatives, Whorf drew upon his studies of the Hopi and Maya languages and cultures; asserted a close interrelationship among language, culture, and thought; integrated wisdom and esoteric traditions; challenged core tenets of Western science; and incorporated interdisciplinary research into linguistics. In critiquing many traditional linguistic and scientific assumptions of his era, Whorf's writings foreshadowed much current research in cultural studies, cognitive psychology, anthropological linguistics, and consciousness studies.

The most detailed biography of Whorf was written by John B. Carroll as the introduction to his book collection of Whorf's writings (Whorf, 1956). Whorf was born on 24 April 1897 in Winthrop, Massachusetts, a suburb of Boston. He was the eldest of three sons born into a prominent family who descended from the first wave of English settlers to the American colonies. In his primary and secondary education, Whorf developed a lifelong interest in science, particularly in chemistry; and in 1918, he earned a Bachelor of Science degree in Chemical Engineering at the Massachusetts Institute of Technology (M.I.T.). In 1920, Whorf and Celia Inez Peckham married and they had three children.

A year after his graduation from M.I.T., Whorf began his career in fire prevention engineering at the Hartford Fire Insurance Company (HFIC). He was among the first generation of fire safety inspectors in the insurance industry, and his fire prevention consultation was highly sought after by a wide variety of manufacturing companies. Whorf's pioneering specialty and acknowledged expertise not only brought him deserved professional recognition in the growing field of fire prevention, but it also attracted many clients to the HFIC. Because Whorf contributed substantially to its business growth, the HFIC retained his services by regularly granting him long- and short-term leaves to pursue his scholarly research in linguistics. Whorf apparently valued this unconventional career arrangement with HFIC because he never left the company to accept an academic appointment, and he remained in the employ of HFIC until his death in 1941. Whorf's professional standing as a chemical engineer as well as his education in the sciences provided him with a capacity for scientific inquiry and analysis not typically found in a linguist. By drawing on his science vocabulary, he consistently introduced linguists to scientific words and metaphors as he described and analyzed the complex systems and structures of language.

Whorf met Sapir in 1928, and they became research collaborators in 1931 when Sapir left the University of Chicago to join the faculty at Yale University, which is located in Whorf's hometown of Hartford, Connecticut. Whorf enrolled in the first course in American Indian linguistics taught by Sapir at Yale, and he was inspired by Sapir to study Hopi, a language related to Aztec (Darnell, 1990). Although Whorf studied with Sapir, the two never collaborated on a presentation or a publication on linguistic relativity. Thus, the term Sapir–Whorf Hypothesis is a misnomer. In fact, while Sapir was interested in the relationship among language, thought, and culture as was his teacher Franz Boas (1858–1942), he was not nearly as committed to the notion of linguistic relativity as Whorf. For Whorf, his extensive research on linguistic relativity was clearly the core passion of his scholarly life.

Whorf engaged in extensive anthropological research by working in the renowned Native American collection at the Hartford Public Library. He renewed his interest in Mexican languages, especially Aztec and Maya. In 1929, he became a member of the Linguistic Society of America (LSA); and in the first year of his membership, he presented a paper on Maya lexical stems at the annual meeting of the LSA. Soon after this presentation, he received his first research grant to study the Mayan ruins in Mexico.

With the exception of Sapir's courses at Yale, Whorf was self-taught in linguistics. While he was never appointed to a faculty position, Whorf was not an amateur scholar in the traditional sense: he lectured frequently at Yale and other universities, taught Sapir's course at Yale when Sapir was on sabbatical leave, participated in a broad range of academic circles and organizations, held distinguished honorary appointments and offices, received credible academic grants, and presented and published scholarly papers and reports. As evidence of Whorf's prominence in the linguistic community, George Trager, eminent professor at Yale as well as Whorf's collaborator and friend, wrote an obituary for Whorf in *Language*, the journal of the LSA.

Whorf's research focused on two general areas: the Hopi and Mayan cultures and languages, and the integration of language, thought, and culture. For the most part, he connected the two areas because he usually drew on his research on Hopi and Maya to exemplify aspects of his theory of linguistic relativity. As for the former area, the Hopi and Maya languages provided him with many illustrative examples of non-Western world views that supported his persistent critique of the assumptions of Western science. As for the later area, Whorf argued that the interplay of language, thought, and culture enabled the process of mental growth in the human development. He regarded

mental growth as essential for the quality of cognitive development required to solve human problems, both present and future. Whorf insisted that the survival of the human species as well as that of the environment was totally dependent on the evolution of thinking and cognition.

In 'An American Indian Model of the Universe,' Whorf (1956) provided an example to explain the bond between language and thought in his theory of linguistic relativity: he pointed out that the Hopi language, unlike Western languages, did not have traditional verb tenses. He used this distinctive grammatical feature of the Hopi language to develop his case against the notion of linguistic and/or cultural universals. Whorf indicated that Hopi speakers who knew only the Hopi language and the cultural ideas of their society did not have the same concepts of time as those held by speakers of English. Specifically, Whorf stated that a Hopi speaker did not have an understanding of time as a smooth flowing continuum in which everything in the universe proceeded at an equal rate from past to present to future, or in reverse order. While his example of verb tenses has often been disputed, even ridiculed, by various linguists, it has not been disproven.

Whorf noted that Hopi did not contain words, phrases constructions, or verbal expressions that directly referred to the concept of time as well as to the notions of past, present, or future. Rather than viewing Hopi speakers as trapped in flawed metaphysics and speaking a deficient language, Whorf argued that the Hopi had a consciousness of time and space that was simply different than that of a speaker of English. Based on this conclusion, Whorf claimed that the Hopi viewed the universe through a different lens than speakers of other languages. This observation supported Whorf's thesis that there were ways of perceiving the universe other than those enshrined in traditional Western science. Because Whorf believed that worldviews were determined culturally and linguistically, he argued that one could understand the worldviews of others only by opening oneself to other cultures and languages. He asserted that the structure of English, like that of all languages, layered its distinct metaphysical systems on the world.

In 'A linguistic Consideration of Thinking in Primitive Communities,' Whorf (1956) explained his principle of linguistic relativity by focusing on what he believed were the cognitive and rational processes that affected thinking. He indicated that anthropological linguists were the most knowledgeable scholars of these processes because in their research they explored those aspects that were primarily related to language and culture. In particular, he cited Boas, Sapir, and Leonard Bloomfield (1887–1949) – scholars whom he considered among the leaders in this emerging area of research.

In addition to the work of the anthropological linguists, Whorf recognized the research of those in the field of psychology in general and the work of Carl Jung (1875–1961), in particular. Whorf claimed that psychologists contributed significantly to advancing his theory of linguistic relativity. In particular, he was drawn to Jung who maintained that of the four psychic functions; two were rational (thinking and feeling) and two irrational (sensation and intuition). Throughout his writings, Whorf referred to Jung's psychic functions to support his idea that the study of language was the most appropriate path leading to a thorough and reliable understanding of thinking.

Whorf believed that linguists were primarily driven by their persistent search for meaning, and he believed that the discipline would eventually draw upon more scholarship from psychology and cultural studies. He emphasized that importing data from other disciplines into linguistics would add, not detract, from its scientific status. He was strongly convinced that linguistics would always retain its scientific precision in its analysis of language structure. He envisioned a day when linguists would eventually become aware of the many psychological undercurrents that have made an impact on individuals and groups throughout history. To support his thesis, Whorf presented a brief history of linguistics in which he emphasized the psycholinguistic patterning of language as an essential part of culture. He contended that the study of language from the ancients to the twentieth century could be characterized as developing merely formal and overt structures. He indicated that a debt of gratitude was owed Boas because in his *Handbook of American Indian Languages* (1911), he was the first linguist to analyze a language on its own terms and not force a traditional and classical model on it.

In 'A Linguistic Consideration of Thinking,' Whorf (1956) clearly expressed his notion that human thinking, like other human capacities, was continuing to evolve. He noted that an evolution of thinking was necessary in order for the human species to preserve itself as well as its environment. He argued that a history of mental growth could be found in the history of each language because languages have their own systems for discerning, selecting, and thinking. Similar to Owen Barfield (1898–1997) who in his *History in English Words* (1926) stated that an evolution of consciousness could be found in the history of the lexicon of a language (Subbiondo, 2003), Whorf vigorously defended the notion that language was the ultimate inroad to understanding an evolution of thinking, and he compared the status of research of mental growth in his day to that of pre-Linnaean botany.

In order to advance his theory of linguistic relativity, Whorf developed a case for a new scientific paradigm in 'Language, Mind, and Reality' (Whorf, 1956). Whorf's paradigm was based on an acceptance of many and varied multiple logical systems underling the grammatical structures of the world's languages. Whorf's principal criticism of Western science was not based on its conclusions but on its methodological analyses of the universe. He was convinced that Western methods of analyses were severely limited by the primary assumption of Western scientists that there was a universal logic. Whorf declared that the way for Western scientists to transcend their notion of a universal logic was that they needed to recognize the existence and validity of alternative logical systems. He held that if one could accept alternative logical systems, one could appreciate other worldviews, which could provide fresh insights into all aspects of reality.

In 'Science and Linguistics,' Whorf (1956) argued that because each language had its own logical system, there were as many logical systems as there were languages. He pointed out that in their studies of the background phenomena of language, comparative grammarians discovered that the notion of language universals was false because no feature was common to all languages. He maintained that the grammatical structure and the lexicon of each language did more than shape the expression of ideas, it shaped the content of ideas as well. For Whorf, ideas were dependent upon the language in which they were conceived and expressed.

Whorf documented the fact that comparative grammarians in studying nonIndo-European languages (he cited Semitic,

Chinese, Tibetan, and Hopi) discovered that each language had its distinct worldview. He illustrated his point by specifically referring to Hopi to show that measurements of time and velocity were different to a Hopi speaker than to a speaker of Western languages. Moreover, he cautioned that by privileging the worldview of speakers of Indo-European languages, one was encouraged to overlook the unique panorama of worldviews embedded in other languages. Moreover, Whorf held that by privileging Western languages as the sole model for all languages contributed to what he perceived to be sheer intellectual arrogance that prevented people from being receptive, authentically curious, and sufficiently detached toward expanding their perceptions and thoughts.

In 'Linguistics as an Exact Science,' Whorf (1956) argued that science could make measurable progress, if it would focus not on changing the facts but on changing how one thought about the facts. He specifically cited the findings of Bloomfield who asserted that language played an indispensable role in advancing scientific progress. Bloomfield explained that scientific research started with a set of sentences that recorded specific observations. After extensive experimentation, the findings would become part of the scientific record when they were expressed in another set of sentences, which then served as the basis for further research through more experimentation. Like Bloomfield, Whorf understood that there could be neither science nor scientific progress without language.

Whorf concluded that because linguistics was an experimental science, it fully deserved the academic prestige and financial support that was provided by physics and chemistry. He noted that similar to their colleagues working in the other sciences, linguists collected data, experimented with human subjects, and formulated verifiable conclusions. Moreover, he maintained that the subject matter of linguistics, language, shaped as well as expressed the totality of human agreement and learning.

In 'Language and Logic,' Whorf (1956) focused his attention on the nature and structure of alternative logical systems in various language and their role in shaping diverse worldviews. He argued that differences in languages were reflected in different interpretations of facts. Whorf believed that one understood facts according to the worldviews embedded in one's language. Drawing on his knowledge of chemical engineering, Whorf compared languages to the two types of mixtures of material substances: mechanical and chemical. He pointed out that a mechanical mixture of a material consisted of adding any ingredient that did not change the appearance of the material. A chemical mixture, on the other hand, was made up of mutually suited materials that overtly changed the appearance of the material. After considerable discussion, Whorf classified English as a mechanical language and Shawnee as a chemical language. He pointed out that the logical system of English like its Indo-European relative, Greek was based on a mechanical mixture; and he facetiously added that its logical system would have been chemical if Aristotle were a Shawnee.

Whorf believed that reality in its fullest dimensions could not possibly be explained by the logical system of any one particular language, no matter how expansive its logical system. He maintained that the generations of Western cultures have expressed no more than provisional analyses of reality even though each generation had resolutely determined that its analysis was final. Whorf argued that plausible correctives to this 'final' analysis were in the various non-Western languages and these languages had also evolved over the centuries independent of Western languages. As a consequence, the speakers of non-Western languages arrived at a different, but equally logical, analysis of reality. Whorf maintained that the principal benefit of understanding the alternative logical systems of non-Western languages was that they could advance scientific inquiry. It was possible, in Whorf's view, that non-Western languages could lead to plausible understandings of complex scientific issues that would be inexpressible in Western languages. Whorf stressed repeatedly throughout his writings that languages differed not only in their constructions of sentences but also in the imaginable content of their sentences. In Whorf's time as today, there was a strong allegiance to the infallibility of universal logical reasoning; and any suggestion to the contrary, as was clearly the case for Whorf's principle of linguistic relativity, was often met with fierce and dismissive resistance.

In 'Language, Mind, and Reality,' Whorf wrote what has been regarded by many as his most controversial essay because in it he proposed an overarching view of linguistics that included references to Indic philosophy and spirituality that were contained in esoteric wisdom texts. The essay was published a year after his death in the *Theosophist*, the publication of the Theosophical Society. The Society was initially formed in New York City in 1875 by Helena Blavatsky among others to explore mystical teachings and practices. After a few years, the Society moved its headquarters to Chennai (formerly Madras), India. In time, the Theosophists studied a full range of Eastern religions and forms of spirituality, especially Hindu and Buddhist teachings and practices. The Society gradually formed a global community that was open to all people regardless of race, creed, gender, caste, and color. In light of the social mores of the time and the prevailing legal support for discrimination, the Theosophists were a group offering a radical social agenda of complete inclusion. In addition to the study of world religions, the group also encouraged the study of philosophy and science.

The breadth and depth of Whorf's lifelong reading of esoteric texts influenced his thinking about language and shaped his theory of linguistic relativity far more than scholars have typically acknowledged (Joseph, 2002). As a young man, Whorf discovered the work of Antoine Fabre d'Olivet (1768–1825), an obscure French philologist and mystic who taught that the root ideas of ancient Judaic spiritual thought were embedded in Hebrew letters. Whorf was fascinated by the work of d'Olivet because he was very interested in biblical studies. It can be safely argued that Whorf's inspiration to study language was religious. Whorf was convinced that d'Olivet's method of biblical study was similar to the structural approach that dominated linguistics in his day. Whorf's reading of d'Olivet prompted him to study Hebrew in order to better appreciate and evaluate the legitimacy of d'Olivet's claims.

The archival collection at Yale contains extensive materials that document Whorf's lifelong interest in the work of the Theosophists in particular and in spiritual and religious traditions and practices in general. Whorf's study of esoteric wisdom was aligned with his lifelong personal and professional commitment to understanding multiple logical systems. In

light of the emerging interest in Eastern thought currently, Whorf's considerable attraction to the study of mysticism is more acceptable to scholars today than it was in his own day. The fact that this aspect of Whorf's research was not mentioned in any detail by Carroll in his biography of Whorf strongly suggests that his supporters were understandably concerned that Whorf and his work might not be taken seriously if his connection to the Theosophists were common knowledge. Scholars in this century warn that it would be a mistake to treat Whorf's discussion of Eastern ideas superficially – they had a significant impact on his work (Lee, 1996).

Drawing on the notion of the Indic mantra as a formulaic expression in language, Whorf argued that language structures and grammars represented cosmic patterns and arrangements. Whorf was well aware that this perspective drawn from the Yoga tradition was new to Western scientists and would probably be rejected outright; nonetheless, he insisted that the notion of the mantra was based on unimpeachable evidence. He pointed out that an individual's thoughts were controlled by unconscious laws of patterning, which affected intricate logical systems. These logical systems channeled reasoning and built the structure of consciousness in each person as well as in every culture. While Whorf recognized differences in logical analyses spawned differences in worldviews, he insisted that all humans had equal analytical capacity.

In this final article, Whorf summed up the central theme of the essays written at the end of his life: namely, the study of language was critical to the study of thinking and cognition. Whorf argued that there was an urgent need for linguists not only to learn diverse languages but also to understand the diverse worldviews that flowed from these languages. He claimed that only through clearly unbiased research of language, one could discover in non-Western languages profound, effective, and scientific expressions unknown and unthinkable to those who speak Western languages.

From the 1950s to the 1990s, the transformational generative grammar of Noam Chomsky with its emphasis on language universal dominated linguistic theory in the United States and elsewhere. Because Whorf's theory of linguistic relativity was antithetical to the generative grammarian's theory of language universals, his work was disputed if not dismissed by leading generative linguists (Pinker: 1994). In fairness one could argue that Whorf was often read out of context and quoted in isolated statements. Nonetheless after Whorf's death, most anthropological linguists as well as psycholinguists often referred to Whorf's work as their starting point and either supported or rejected in part or in whole his principle of linguistic relativity (Lucy, 1992). With the current interest in consciousness studies and the focus on language in studying the nature and structure of consciousness, Whorf's work has become of interest once again to many contemporary scholars (Gumperz and Levinson, 1996).

Although Whorf engaged himself in an ambitious conceptual enterprise, his theories and lines of reasoning have become more accessible to scholars in recent times than when they were originally developed (Lee, 1996). For example, it is common knowledge today that people in non-Western cultures view the world differently than do those in Western cultures. While how much language affects culture may be debatable, most scholars would agree that culture shapes worldviews. This conclusion which was strongly argued by Whorf has come about mainly due to an extraordinary increase of late in studies of non-Western cultures by Western scholars and drawing from them fresh perspectives that can be applied in many areas of research (Nisbett, 2003).

Whorf's writings foreshadow the current trend in the academy to integrate interdisciplinary research into mainstream scholarship. References to Whorf's work can be found in disciplines outside linguistics including philosophy, psychology, and cultural studies. In addition to interdiciplinary research, there are many more disciplinary blends today than there were in Whorf's time: for example, psycholinguistics (a term first used by Whorf). The accelerating increase in interdisciplinary studies in the present century has contributed in large measure to advances that could not have been made possible or even imagined within the confines of traditional academic disciplines. For example, the study of language and consciousness could not have flourished without the convergence of biology, linguistics, neuroscience, philosophy, and psychology (Wardy, 2000). In many aspects, the intedisciplinarity of current scholarly research reflects a breadth of integrated learning that Whorf envisioned nearly a century ago.

Abstract

Williams syndrome (WS) is a rare neurodevelopmental disorder, caused by a hemizygous deletion of 26–28 genes on chromosome 7. It is of particular interest to neuroscience because of its uneven cognitive profile and the hope of mapping genotype/phenotype relations. The article describes important aspects of the WS neural and sociocognitive profile from infancy to adulthood.

In the final decades of the twentieth century, cognitive neuroscience paid particular attention to a group of disorders known as microdeletion syndromes. These are neurodevelopmental disorders in which the missing genes on a chromosome can be identified and the resulting gene–behavior relations explored. They differ from syndromes like autism and dyslexia, which are likely to involve a very large number of genes of small effect. One microdeletion disorder that caused particular excitement among cognitive neuroscientists is Williams syndrome (WS). This is because WS results in an uneven cognitive profile. Language and face processing are seemingly spared, whereas other higher cognitive functions (e.g., spatial cognition, number, planning, and problem solving) are seriously impaired. Initial characterizations of the syndrome at the cognitive level seemed to hold the promise of relatively straightforward gene-cognition mappings. WS was, and continues to be by some researchers, hailed as the prime example of intact, independently functioning cognitive modules in the face of general intellectual impairment (e.g., Bellugi et al., 2000; Landau et al., 2006; Musolino et al., 2010; Pinker, 1994; Tager-Flusberg et al., 2003). However, more recent evidence challenges this view, favoring instead a more dynamic, neuroconstructivist approach to genetic disorders (Karmiloff-Smith et al., 2012a). In this article, data on the neural and cognitive processes underlying the purportedly spared domains will be examined, together with a focus on the infant phenotype and the developmental trajectory leading to the phenotypic outcome.

Williams Syndrome: Genetic Profile

Williams syndrome is a rare neurodevelopmental disorder occurring in approximately 1 in 20 000 live births (Pober, 2010; although see Strømme et al., 2002 for an estimate of higher prevalence), involving a hemizygous deletion of 26–28 genes on chromosome 7q11.23 (Pober, 2010). Clinical symptoms are wide-ranging, including dysmorphic facial features, supravalvular aortic stenosis (SVAS), dental abnormalities, gastrointestinal and endocrine problems, and hypersensitivity to sound (Pober, 2010) as well as an uneven cognitive profile (Mervis and John, 2010). The gene for elastin (*ELN*) within the deleted region (Ewart et al., 1993) remains the only clear-cut genotype–phenotype mapping, contributing to SVAS and general connective tissue problems (Pober, 2010). Another of the deleted genes, Limkinase1 (*LIMK1*), is expressed in the brain and was initially claimed to be implicated in spatial cognition deficits (Frangiskakis et al., 1996). However, Gray and colleagues assessed two partial deletion patients (only *ELN* and *LIMK1* deleted) on a range of spatial abilities, comparing them to two participants with the full WS deletion who presented with strong verbal abilities. The individuals with WS continued to display the characteristic WS profile of weak spatial skills, while the partial deletion patients did not, leading to the conclusion that the *LIMK1* gene is either not implicated in spatial cognition, or if involved, it is through interaction with other genes in the Williams Syndrome Critical Region (WSCR) (Gray et al., 2006). Currently, four telomeric genes in the WSCR, all transcription factors, are thought likely to be the most critical contributors to the WS sociocognitive phenotype (Karmiloff-Smith et al., 2012b), involving complex cascading effects. Clearly, the way in which genes in the deleted region impact upon the eventual phenotype is complex and dynamic, involving widespread, low-level and interactive effects of gene expression over time (Karmiloff-Smith, 1998), rather than a direct one-to-one genotype–phenotype mapping.

Williams Syndrome: Phenotypic Profile

The pioneering work of Bellugi and collaborators initially pinpointed some clear-cut dissociations in the cognitive architecture of WS. Language and face processing appeared to be preserved in the face of both general retardation and particularly serious problems with visuospatial cognition. These apparent dissociations continue to be highlighted by some authors (Bellugi et al., 2000; Tager-Flusberg et al., 2003), while most researchers in the field of WS have been fairly cautious about their claims, referring to relative strengths and weaknesses rather than absolute ones (Karmiloff-Smith, 1998; Mervis and John, 2010). By contrast, secondary sources cited in writings by linguists, developmental psychologists, neuropsychologists of adult brain damage, and philosophers have often used WS to bolster claims about innately specified,

independently functioning modules, some of which are purportedly intact and others impaired (e.g., Clahsen and Almazan, 1998; Pinker, 1994). This stems from the view that the pattern of behavioral performance found in the phenotypic outcome is a direct window on the innate, modular structure of the brain's cognitive architecture (Baron-Cohen, 1998; Temple, 1997).

Advances in brain imaging technology have facilitated examination of the structure and function of the WS brain, revealing that it is qualitatively different from normal brains (see Karmiloff-Smith, 2010 for discussion) in terms of brain anatomy (Bellugi et al., 2000), brain biochemistry (Meyer-Lindenberg et al., 2006; Rae et al., 1998), and computational processing (Mills et al., 2000). WS brains show reduced brain stem and overall brain volumes, with normal proportional cerebellar and superior temporal region volumes (Reiss et al., 2004). The complexity of cortical folds is increased in WS relative to controls. Abnormalities of the corpus callosum and hippocampus (Meyer-Lindenberg et al., 2006) have also been reported. Attempts have also been made to link specific brain abnormalities to particular strengths and deficits in the WS sociocognitive phenotype. For example, Meyer-Lindenberg et al. (2006) aimed to identify separable neural subsystems for visuospatial cognition, social behavior and memory, which they deemed to be under genetic control. The approach taken in this and other studies (e.g., Germine et al., 2011; Musolino et al., 2010) tends to treat the atypically developing brain as if it were a normal adult brain with parts intact and parts impaired, ignoring the developmental history of WS in terms of the dynamic role of genetic mutations in interaction with environmental input in fostering overall brain growth over developmental time. Interestingly, although most research on WS brains has focused on adults and adolescents, a recent MRI study of older children with WS found increased complexity as well as reduced surface area and cortical volumes compared to healthy controls (Fahim et al., 2012). Studies of the early stages of WS brain development are rare (but see Boddaert et al., 2006), yet they are critical if we are to understand the relationship between the WS developing brain and the cognitive phenotype, because both progressively change over developmental time (Karmiloff-Smith, 2010).

We now examine language and the social domains for which some authors have claimed that the syndrome eloquently illustrates selectively intact processing alongside general intellectual impairment. However, even in cases where the phenotypic outcome in adults seems to display intact performance, in-depth analyses now suggest that individuals with WS process inputs via different neural and cognitive processes compared to healthy controls (Karmiloff-Smith, 1998; Karmiloff-Smith et al., 2004).

Language Development

Notable is the fact that although WS language ends up relatively fluent in the adult phenotype, the time course of WS language acquisition is significantly delayed (Mervis and John, 2012). Although at 2 years of age WS expressive vocabulary size is larger than that of chronological age (CA)-matched toddlers with Down syndrome (DS) (Mervis and John, 2012), the onset of vocabulary in toddlers with WS is seriously delayed relative to norms on the Communicative Development Inventory (Fenson et al., 1993). Moreover, infant precursors to language, such as babbling, are delayed in WS (Masataka, 2001). Finally, early WS vocabulary production precedes referential pointing, the opposite to the normal order of acquisition (Laing et al., 2002; Mervis and John, 2012).

Despite these early delays, it is notable that older children and adults with WS perform well on tests of receptive vocabulary, such as the Peabody Picture Vocabulary Test – Revised (PPVT-R; Dunn and Dunn, 1981). Indeed, PPVT-R scores in WS are generally above the level expected for their mental age (MA) (e.g., Brock, 2007). However, while better than expected for MA and strength relative to other areas of language, WS vocabulary falls well below CA (Mervis and John, 2012). Moreover, vocabulary in WS is not simply delayed, but also atypical. Language with a spatial component poses particular difficulties for individuals with WS (Phillips et al., 2004), while for young children with WS, more general conceptual/relational vocabulary knowledge (rather than specifically spatial knowledge) is weaker than their concrete receptive vocabulary (Mervis and John, 2012). Several studies now suggest that there may be an imbalance between phonology and semantics in WS (Karmiloff-Smith, 1998; Thomas and Karmiloff-Smith, 2003). For example, when WS participants monitor sentences for a target word, they do not show sensitivity to certain sentential violations, suggesting that semantic information may become available too slowly to be integrated with the online processing of syntax (Tyler et al., 1997). A study of reading in WS came to similar conclusions about the weak role of semantics (Laing et al., 2001). The control group found concrete, imageable words much easier to read than abstract words, but the WS participants failed to benefit from the imageability of the concrete words, displaying equal levels of (poorer) reading for both concrete and abstract words. In general, imageability effects have been shown to be weaker in people with WS than in typical development. A study by Vicari and his colleagues demonstrated that, compared to normal controls, word learning is superior in WS if the auditory presentation of a word is accompanied by the simultaneous presentation of a photograph depicting the object (Vicari and Carlesimo, 2006), whereas healthy controls easily create images mentally when they hear words. There is also evidence for lower levels of audiovisual integration in WS than typical development (TD) (Böhning et al., 2002). Taken together, a variety of studies suggest that, unlike typical development, phonological representations weigh more strongly than semantic representations in WS language acquisition over developmental time. In the domain of syntax, WS adults tend to display patterns typical of much younger children (Mervis and John, 2012). Earlier it had been claimed (Clahsen and Almazan, 1998) that individuals with WS have intact regular past tense formation of verbs, alongside impaired associative lexical processes. More recent research challenges this claim, in that once verbal MA is taken into account, no selective deficit for irregular verbs emerges in WS (Brock, 2007; Thomas and Karmiloff-Smith, 2003).

Despite the growing database on WS language, some continue to claim that WS syntax is intact (e.g., Musolino et al., 2010; Pinker, 1994). There are, however, a number of lines of evidence to challenge this. First, when WS vocabulary and syntax are compared to norms for healthy individuals, WS

vocabulary levels are usually better than their syntactic levels on various standardized tasks, suggesting an imbalance between the two (Brock, 2007; Mervis and John, 2012; Vicari and Carlesimo, 2006). Second, even in very simple imitation tasks, participants with WS show impairments with complex syntactic constructions such as embedded relative clauses (Grant et al., 2002; Vicari and Carlesimo, 2006). Moreover, even in an area of relatively simple syntax – grammatical concord – which normal French-speaking children acquire easily and very early in development, individuals with WS show deficits even in adulthood. Although the WS participants learned the local gender marker (correct article) for a nonce term easily (in fact, more easily than controls), their capacity for gender agreement across sentence elements, such as grammatical concord on adjectives or pronouns, was seriously impaired (Grant et al., 2002). Studies of Italian-speaking children (Volterra et al., 2003) have also revealed that grammatical gender presents a particular problem, with WS children displaying errors that are never encountered in normal development at any age. Finally, several studies (e.g., Karmiloff-Smith et al., 1997; Mervis and John, 2012; Vicari and Carlesimo, 2006; Volterra et al., 2003) suggest that the problems that people with WS have with semantics and syntax are often camouflaged by their good verbal memory.

These various findings are consistent with the hypothesis that the WS language system is not only seriously delayed, but also atypical, because it has developed under different constraints (Thomas and Karmiloff-Smith, 2003). In sum, the relatively impressive WS language found in adulthood may well be acquired through alternative, compensatory routes involving different neural processes.

Social Development

Despite reports that WS face processing is intact (Bellugi et al., 2000; Tager-Flusberg et al., 2003), in-depth studies of face processing suggest that individuals with WS use different strategies from normal controls (Karmiloff-Smith et al., 2004). Several studies (Deruelle et al., 2003; Karmiloff-Smith, 1998; Karmiloff-Smith et al., 2004) have replicated earlier work, revealing normal or near normal behavioral scores on standardized tasks like the Benton Facial Recognition Test (Benton et al., 1983) and the Rivermead Behavioural Memory Test (Wilson et al., 1985). However, experimental approaches alongside the standardized tasks have seriously challenged the notion that the WS behavioral success in face processing tasks is subserved by normal cognitive and neural processes. Where normal controls use predominantly configural strategies for processing upright faces, and featural strategies for processing inverted faces, individuals with WS tend to process both upright and inverted faces featurally. While subsequent studies have found good scores on holistic face processing in WS (Tager-Flusberg et al., 2003), a distinction should be drawn between holistic face processing and configural face processing: the former involves the gluing together of facial features (and hairline) into a gestalt (first-order information), without necessarily computing the spatial distances between features, whereas the latter involves the ability to differentiate faces based on sensitivity to the spatial distances among internal features, i.e., second-order relational information (Karmiloff-Smith et al., 2004). While there is indeed evidence of typical-looking holistic face processing in WS, albeit only in adulthood (Deruelle et al., 2003; Tager-Flusberg et al., 2003), a series of experiments demonstrated that configural face processing is difficult for individuals with WS and that it does not develop with age in the same way as for controls (Karmiloff-Smith et al., 2004). This is also supported by evidence from brain imaging studies. When electrophysiological measurements were taken while older children and adults with WS processed faces in an event-related potential study, they tended to process them bilaterally or predominantly with the left hemisphere, whereas healthy controls showed a right hemisphere bias for faces (Mills et al., 2000). Furthermore, an EEG study of face processing by Grice et al. (2001) yielded patterns of gamma-band activity in individuals with WS that were very different from controls. While the controls showed regular gamma bursts tied to stimulus onset, gamma-band activity in WS was almost flat. This suggests that binding of perceptual features in WS is impaired, thus contributing to their difficulties with configural processing. All of these findings point to atypical face processing in WS, despite the normal behavioral scores on standardized tests.

Face processing is not the only area of the social domain that is atypical in WS. Individuals with WS are often described as having a characteristic social, over-friendly personality, i.e., a 'hypersocial' profile at all ages from infancy to adulthood (Doyle et al., 2004; Jones et al., 2000). This adversely affects WS adults' rating of stranger approachability (Jones et al., 2000; Martens et al., 2008). Moreover, they also have difficulties with social interactions and peer relationships (Campos and Sotillo, 2012; Stinton and Howlin, 2012; Stojanovik, 2006), and their communicative language reveals serious impairments in pragmatics (Laws and Bishop, 2004). Importantly, Jawaid et al. (2011) highlight the social vulnerability and high levels of abuse and social isolation experienced by individuals with the disorder, in part due to atypical gaze behaviors and over-friendliness. In contrast, and seemingly at odds with their eagerness to interact in social situations, anxiety disorders occur at a high level in WS (Mervis and John, 2010; Stinton and Howlin, 2012).

Cognitive Development

Full-scale IQ is within the mild-to-moderate range for most individuals with WS (Martens et al., 2008). However, given the uneven language/spatial profile in WS (Mervis and John, 2010), it is more informative to measure verbal and nonverbal skills separately for this group (for discussion, see Mervis and John, 2010). Indeed, the uneven cognitive profile in WS makes it especially important to carefully consider the implications of experimental designs when selecting matched groups (Hudson and Farran, 2012), which can be surmounted by using the developmental trajectories approach (Thomas et al., 2009).

In the domain of memory, the verbal/visuospatial discrepancy observed in WS (e.g., Phillips et al., 2004) is also reflected in their performance in short-term memory tasks, although only in adolescents and adults, and not in younger children (Vicari and Carlesimo, 2006). Executive function abilities are generally poor (Menghini et al., 2010; Rhodes et al., 2010).

Similarly, visuospatial construction is especially impaired in WS (Landau et al., 2006), even when compared to their already poor level of nonverbal ability (Phillips et al., 2004). Moreover, Vicari and Carlesimo (2006) provide evidence that unlike DS and TD groups, WS visuospatial memory is poor even after their perceptual skills are taken into account.

Individuals with WS also experience considerable difficulty with number. Infants with WS can discriminate between small numbers, but have more difficulty discriminating large approximate magnitudes (Van Herwegen et al., 2008). They also display atypical scanning patterns when processing numerical displays (Karmiloff-Smith et al., 2012a). Furthermore, while somewhat older children with WS can learn to count, many do not understand cardinality, i.e., the final count word represents the total number in a set. When they are asked, 'how many?' just after counting a set, they merely start to count the objects all over again. Moreover, the ability to understand cardinality is predicted by language levels in WS, whereas it is predicted by spatial scores in typical control children (Ansari et al., 2003), suggesting different developmental trajectories.

Drawing practical implications from experimental work is important, such as finding one's way around the environment. Farran and colleagues recently studied navigational skills and asked individuals with WS to learn a real-life route. They found that although the WS participants were able to learn the route after practice, they were less successful at creating a mental map, which would have allowed them to work out a short cut (Farran et al., 2010).

Finally, John and Mervis (2010) demonstrated that children with low levels of sensory deficits were less impaired in executive functioning, temperament, adaptive functioning, and problem behaviors than those with high levels of sensory deficits. Attention is also a capacity that also shows an atypical developmental course in WS (Beckenridge et al., 2012). These findings constitute examples of low-level general impairments, which have cascading effects on the outcomes of specific cognitive domains.

Concluding Comments

The WS brain is 20% smaller than normal brains and qualitatively different in terms of brain anatomy, brain function, brain biochemistry, and computational processing. This holds throughout embriogenesis and postnatal brain development and means that interaction with environmental stimuli is likely to be subtly different. Given a different brain, it is unsurprising that even when overt behavior looks as if it were normal, as in some aspects of WS language and face processing, these skills actually turn out to be underpinned by cognitive and neural processes that are different from the normal case. Early low-level impairments may underlie later-developing skills, and performance can and does change over developmental time (Karmiloff-Smith, 1998; Karmiloff-Smith et al., 2012a). Delineating changes in developmental trajectories over time is critical to understanding any neurodevelopmental disorder (Thomas et al., 2009).

Williams syndrome is an excellent model for the neurocognitive study of genetic disorders, because of its known genetic origins and its unusual cognitive profile. The syndrome is especially important because of the way in which in-depth research highlights the need to go beyond both observable behavior and static descriptions of snapshots of development, to charting the full course of neurocognitive trajectories from infancy onward.

Abstract

William Julius Wilson, Lewis P. and Linda L. Geyser University Professor at Harvard University, is one of the best known and widely cited American sociologists of the late twentieth and early twenty-first centuries. His major books, *Power, Racism and Privilege* (1973), *The Declining Significance of Race* (1978), *The Truly Disadvantaged* (1987, revised edition 2012), *When Work Disappears* (1996), and *More than Just Race* (2010), all address an abiding personal and professional concern with and critical analysis of two issues, race and poverty.

The sociologist William Julius Wilson, currently Lewis P. and Linda L. Geyser University Professor at Harvard University, has long made outstanding contributions to the study of social inequality and urban poverty in the United States.

Wilson has been given many different labels but the one he claims to feel most comfortable with is 'social democrat.' He especially identifies himself with the approach of late Michael Harrington, Chairman of the Democratic Socialists of America, coiner of the expression 'neo-conservative,' and author of *The Other America: Poverty in the United States* (1962).

The Other America, published in the heady days of the new Kennedy Administration, was for many an exposé of the plight of millions of Americans without jobs, without status, and often without hope. Wilson's far more extensive studies of the same phenomenon indicate that the chasm between those who make it in America and those left behind is as wide as it was 50 years ago. His research and conclusions have influenced two more recent presidents of the United States, Bill Clinton and Barack Obama, and many others inside the government and in the private sector, as well as thousands of students of urban sociology and social policy in this country and around the world.

Early Life and Career

Wilson's personal awareness of the inequities in our society may well have been generated during a childhood spent in the small town of Blairsville in Derry Township in western Pennsylvania where he was born in the depth of the Great Depression on 20 December 1935. He was one of six children whose father – who had worked as a coal miner and in steel mills – died when William was 12 years old. To support the family, his mother sought employment as a housemaid. In various interviews he has described the situation as living in rural poverty, part of the time on relief (social welfare). He studied first at the small, private, historically black AME (African Methodist Episcopal) affiliated Wilberforce University in Ohio, from which he received a Bachelor of Arts in 1958. He went on to do graduate work, first at Bowling Green University (MA, 1961), then to Washington State University in Pullman, Washington, from which he received a Ph.D. in sociology and anthropology in 1966. In those varied environments and during his brief stint doing military service, Wilson was exposed to a considerable cross section of America's people. These experiences doubtlessly had an influence on the perspectives he developed on the nuances and contradictions of social life, leading him to eschew commonplace pigeonholing in his long and active profession as a social scientist.

His teaching career began in Amherst, Massachusetts, where he started as an Assistant Professor at the flagship campus of the University of Massachusetts. While teaching and starting work on the book on the growing socioeconomic gap in African-American communities, he was an active member of the Department of Sociology and of a Five College Committee working on ways to bring Afro-American Studies to each of the campuses in that consortium (Amherst, Hampshire, Mt. Holyoke, Smith colleges, and the University of Massachusetts). In the winter of 1971–72 he published a thoughtful article about "Issues and Challenges of Black Studies," in the *Journal of Social and Behavioral Scientists*. The following fall he moved to the University of Chicago.

While Wilson would later conduct comparative studies looking at race and poverty issues in a number of other metropolitan areas, as was the case during the heyday of Robert E. Park's 'Chicago School of Sociology,' Chicago, the city described in reports such as *The Negro in Chicago: A Study of Race Relations* (1922) by Charles S. Johnson, and such books as Frederic M. Thrasher, *The Gang* (1927), Louis Wirth's *The Ghetto* (1928), Harvey Zorbaugh's *The Gold Coast and the Slum* (1929), and St. Clair Drake and Horace Cayton's *Black Metropolis: A Study of Negro Life in a Northern City* (1945), Chicago would be the major site and anchor point of much of Wilson's own research.

He twice served as Chairman of the University of Chicago's Department of Sociology (1978–81 and 1984–87), spent the next academic year as a Fellow at the Center for Advanced Study in the Behavioral Sciences in Stanford, California, and the fall of 1983 as Langston Hughes Visiting Professor at the University of Kansas in Lawrence, Kansas. Upon his return to Chicago, he was appointed Lucy Flower Distinguished Service Professor. In 1990, he became a University Professor as well as the Director of the Center for the Study of Urban Inequality in the University of Chicago's School of Public Policy. He gave up both positions when he joined the Harvard faculty in 1996. Cambridge, Massachusetts has been his home base ever since.

William Julius Wilson's books, articles, and lectures on the roots and persistence of urban poverty have enlightened many

fellow academics and practitioners in the fields of urban economics, social policy, and grassroots social work. While addressing some of the most complex of all the persisting domestic problems in the United States, his writings have a clarity of structure and presentation that offer important grounding for social policy makers and a useful model for graduate students in the social sciences and for those already in the disciplines like sociology, economics, and political science reluctant to eschew arcane language lest they be considered unscientific.

This is not to say that everything Wilson has written or that all of his studies are flawless in their construction, or that his conclusions and opinions based on his studies do not open themselves to critical assessment by others who have looked at similar issues and come to somewhat different conclusions about causes, effects, and remedies. Yet by almost every measure Wilson has altered perceptions of class and race in American society and offered insights that seriously challenge many assumptions about these two critical variables and their impact – especially on city dwellers – over the four decades he has been studying, analyzing, and commenting on these phenomena using a truly integrated historical, economic, and sociological approach.

Wilson's earliest publications – one in the *Pacific Sociological Review* (1964); a second in the *American Sociological Review* (1967) – were not about race or class but concerned with sociological theory and theory construction. He was particularly interested in varied approaches to the study and empirical measurement of norms and values. The first time he published anything on what many think of as *his* subject was an essay, "The Quest for a Meaningful Black Experience on White Campuses," in the literary journal, *The Massachusetts Review* (1969). From then on almost all of his papers, articles, or books have been on race, class, and related matters.

Illustrative of his proclivity for developing paradigms and integrating sociological theory and social concerns, his contribution the book, *Nation of Nations*, published by Random House in 1972, compared and contrasted several dominant themes in approaching what he would later call 'the underclass.' He called his essay "Race Relations Models and Ghetto Behavior." Wilson had already begun to address these matters while working on his first book, *Power, Racism and Privilege: Race Relations in Theoretical and Historical Perspectives*, published by Macmillan in 1973.

During that same time period, Wilson joined me as a co-editor of an already contracted volume of original essays triggered by the famous Japanese film, *Rashomon*, in which different witnesses to a brutal crime were asked to present their views of what they thought they saw and remembered. The idea was to invite a number of black and white social scientists to offer their perspectives on what we were all witnessing in American society circa 1970. Wilson signed on, as did my colleague, the late political scientist, Stanley Rothman. Together we gathered a group of writers and – in some cases, those of persons in assigned roles: black and white professors, black integrationists, city cops, welfare mothers, school teachers, white ethnics, black militants, etc.

Through Different Eyes: Black and White Perspectives on American Race Relations was published by Oxford University Press in 1973.

One of the most important extras was Bill Wilson's sensitive contribution to the Epilogue of the book, an essay called "The Significance of Social and Racial Prisms." There he observed that while it is true that blacks and whites of the general public tend to view American race relations through different eyes, it is likewise the case that within each racial cohort, perceptions vary according to income, occupation, education, and place of residence. And even here, he noted

> There is no simple one-to-one relationship between individuals' views on racial matters and their respective positions in the social structure because racial attitudes are in major measure shaped by an important intervening variable – feelings of apprehension that out-group racial members plan to undermine, encroach on, or challenge in-group claims to certain rights and privileges. People of high social status, for example, tend to be less virulent in their racial attitudes because their position in society is more secure and they have fewer fears that their interests or prerogatives will be jeopardized by out-group racial members.

These sentiments – many reflecting on the widening gap in Black America – would echo and reecho in what he would publish throughout the rest of the twentieth century and into the second decade of the twenty-first century.

The Race–Class Debate

The first of those new works, published in 1978 by the University of Chicago Press, proved to be one of Wilson's most controversial books – not the least because of its stark title, *The Declining Significance of Race*. In a lengthy essay, "The Declining Significance of Race: Revisited and Revised" in *Daedalus* in 2011, a year before the University of Chicago Press published a third edition of the book, Wilson recently reflected on what he had written more than three decades earlier.

His essay begins with a well-known quotation from George Bernard Shaw: "It is better to be criticized and misunderstood than to be ignored." Wilson then restates his basic arguments, noting, for example, that "changes in the system of production and in government policies have affected, over time, black/white access to rewards and privileges as well racial antagonisms" with two significant results: the deteriorating economic conditions of poor blacks and the concurrent improvement of middle-class blacks during three significant eras in American race relations, the last being the years since World War II when "the black class structure began to take on some of the characteristics of white class structure and that economic class gradually became more important than race in determining the life chances of individual African Americans."

In his paper he addresses the concerns of certain critics, such as Jennifer Hochschild, who felt he did not pay as much attention to generational issues as he should have. He quotes Hochschild's comment that "One has not really succeeded in American unless one can pass on the chance for success to one's children." (The sentence may have reminded some readers of the quip that "In the U.S. it is easy to climb the ladder of success if Daddy owns the ladder.") But Wilson claims that there is ample evidence that middle-class blacks have not only been

able to pass their successes on to their children but have advantaged them in other ways as well.

Wilson also responds to Michael Hout, who had pointed out, while not gainsaying Wilson's basic thesis, that much of the mobility that took place among middle-class blacks was in the public rather than the private sector, and that much more weight should be attributed to 'affirmative action' programs implemented in the 1960s to account for widening rather than narrowing the gap.

Wilson mentions the criticisms of others who had argued that his thesis does not jibe with hard data on differentials between whites and blacks in job security and income in the years since the first edition of *The Declining Significance of Race* was first released, even though the majority noted that 'class does matter.' He concedes that there is some justification in what they say and notes that the biggest changes that have occurred in the number of government jobs available to blacks and whites and the waning enthusiasm for 'affirmative action' in both public and private sectors and that the black class structure increasingly reflects gender differences, especially among younger blacks, as males have fallen behind females on a number of socioeconomic indicators: employment rates, the imbalanced ratio of females to males who complete high school, and average income, with some of the sharpest discrepancies at the lower end of the income hierarchy.

Withal, at the end of his self-critical review Wilson noted that, "If I were writing the *Declining Significance of Race* today, I would provide more balance in my policy recommendations by placing much greater emphasis on the need to *strongly* and *continuously* embrace, as well as advance, both race- and class-based solutions to address life chances for people of color." (Italics are Wilson's.)

Considering "The Truly Disadvantaged"

What Wilson had variously referred to as an 'underclass' and 'the ghetto poor' is graphically captured in the title of his next book, *The Truly Disadvantaged*, also published by the University of Chicago Press (1987). A new edition would be released in 2012.

Addressing "The Inner City, the Underclass, and Public Policy," it was – and remains – a landmark contribution to the literature. Some reviewers said it was Wilson's *magnum opus*. When first published, it was far more widely discussed by politicians, pundits, and the public than his book, *The Declining Significance of Race*, which was read and debated mostly in academic circles.

In the pages of data-rich *The Truly Disadvantaged*, Wilson zeroed in on the interplay among three critical variables: race, employment, and education. The volume is in many ways a clear extension and refinement of concerns underlying his basic premise about changes within the black community and the wider society.

Based on a close examination of both hard and soft data, the author argued that increasing general prosperity and a lessening of racial discrimination enhanced the opportunities of many members of the middle class, including many upwardly mobile African-Americans. They not only began to move up, they also moved out, leaving a great void for those left behind in the inner-city ghettos. More and more young people, especially young men, suffered from the departure of leaders and role models. With fewer and fewer job opportunities, many were drawn into illicit activities, exacerbating the situation and contributing to a breakdown of values, familial and communal ties, and a dramatic increase of various forms of urban plight and pathology, both social and psychological.

Not surprisingly, as he probed more deeply, Wilson found himself revisiting many of the issues raised and enumerated on nearly 20 years earlier by Daniel Patrick Moynihan in his controversial report, *The Negro Family: A Case for National Action* (1964). This subject was also addressed the same year in Kenneth Clark's book, *Dark Ghetto* (1964).

In Wilson's far more detailed study, he also examined the character of the ghetto, the fragility of families, the dramatic increase in one-parent female-headed homes, and the estrangement of both old and young in what both Moynihan and Clark had called a "tangle of pathology." But more than either Moynihan or Clark, Wilson zeroed in on the economic structure and the depressing situation where employment prospects were rapidly disappearing in the very metropolitan areas where for decades blacks, having been displaced by the mechanization of agriculture in the south – and, in no small measure, Jim Crow restrictions – had sought and often found employment with labor-intensive jobs in the north. Then, as new trends in production and the collapse of certain core industries – steel production, automobile assembling, and lighter forms of manufacturing – accelerated, they were again harshly affected. But this time, for workers, especially those without much education, there was no place to which to flee. The ghetto that had become their home often became their jail. This subject would be addressed in much greater detail in Wilson's next major book.

What Happens When Work Disappears

In *When Work Disappears: The World of the New Urban Poor*, published by Alfred A. Knopf in 1996, Wilson presents a case for understanding the plight of the poor based on his analyses of a series of neighborhood studies, detailed interviews and surveys. That data had three major sources: research conducted under the aegis of UPFLS (the Urban Poverty and Family Life Study), the Woodlawn and Oakland Neighborhood Study, and an examination on adolescent social development and the effects of growing up in high-risk neighborhoods.

In the first pages of the book, the author acknowledges and thanks his many colleagues and students at the University of Chicago whose data-sets gave grounding to the examination and analysis of two principal changes in recent urban history: the flight of whites to the suburbs with the subsequent diminution of the tax-base, and, particular institutional changes, particularly the sharp reduction of entry-level opportunities for poor people as businesses and industries also moved out. Concomitant with these causal factors, the author points to their effects not only on the life chances of those left behind in the inner-city but to the demoralizing reality of having fewer and fewer positive role-models within the community and what Wilson sees as the ebbing away of a sense of personal responsibility by those too injured by their plight to mobilize

even the few resources to help themselves. Here he returns to a consideration of the successes and failures of affirmative action programs – programs that clearly had enhanced mobility for those ready, willing, and able to avail themselves of their promise but seemed to do little to attack or mitigate the situation of those left behind and suffering the most alienation in the anomic depths of the black ghettos. (*Note*: It is here where Wilson contributes his own views to the still on-going debates about the implicit bias in affirmative action programs which at present clearly serve the needs of a particular segment within the communities of designated minorities – Asians, Latinos, Native Americans, and especially African–Americans – who are ready, willing, and generally able to take full advantage of such institutionalized gateways. He, along with many others, favors a shift from an exclusively race-based to a more class-based approach.)

Wilson argues that it is not sufficient simply to understand what happens when work disappears, especially in communities that are and have long been terribly vulnerable to patterns of discrimination, poor public services, and low expectations, but it is also necessary to address the extent to which too many inhabitants internalize their marginalized status and act accordingly. As any number of people who have commented on this work have indicated, there is a difference between those who were in fact members of a solid blue-collar working class and found themselves out on the streets and those who, for any number of reasons, never having held steady jobs, were already there.

In a final chapter in *When Work Disappears*, titled "A Broader Vision: Social Policy Options in Cross-National Perspective," Wilson offers some important comparative perspectives on extant programs that simultaneously address the problems of economic growth, joblessness and wage inequality, and programs worthy of emulating in this country. He looks to other societies and their welfare and education systems, especially, in the latter case, those that stress and enthusiastically support school-to-work programs. He ends by offering several concrete policy prescriptions for what to do to address America's problems, many related to general economic conditions and their impact and many a clear remnants of slavery's persisting legacy.

Among a number of policy recommendations regarding the United States, most of which seem to stress the clear requirement that coalitions are needed to move forward, Wilson presses for race-neutral programs geared to jobs creation, further expansion of the earned income tax credits, public school reform, child care programs, and universal health insurance. Recognizing that such will take time – and much intense politicking to achieve their aims, he argues that some matters cannot wait. Most pressing are labor-intensive programs of public service jobs for all workers, and not only those in the inner city with low skills and little or no work experience. This, says Wilson, would help to avoid stigmatization and might broaden the political base of support for the more far-reaching proposals. Such a new New Deal campaign would have as its immediate goal to provide training, jobs, and hope. Finally, linking the discussion of recommended ways of remediating deep-rooted and contemporary problems, the author loops back to his core argument: "My framework for long-term and immediate solutions is based on the notion that the problems of jobless ghettos cannot be separated from those of the rest of the nation."

Here he opened himself once again to criticism by those who have long claimed that the African-American experience is so unique that it must be separated from that of others. He was (is) prepared to weather the storm as he had done earlier in his career when under fire for the use of some highly charged words, not the least, 'underclass,' and more significantly for persisting in stressing the growing significance of class over race in American society.

Wilson's Analyses and Social Policy

Many who reviewed *The Truly Disadvantaged* echoed the sentiments of Robert Greenstein, former Director of the Center on Budget and Policy Priorities in Washington, DC, and published as "Prisoners of the Economy" in the *New York Times* on 25 October 1987. "[The book is] both a rejoinder to what Mr. Wilson regards as flawed conservative critiques and a call to liberals and civil rights leaders to broaden their agendas beyond what he terms the War on Poverty-vision and 'race-specific' policies such as affirmative action." Like Greenstein, many sociologists and economists would also claim that *The Truly Disadvantaged* far surpasses many other attempts to explore the issues of race and poverty. Some, however, would come to agree with Greenstein's statement that "the reader is left with one disappointment. The book's policy prescriptions are less well developed than its powerful analysis of what has gone wrong."

Others said similar things in reviews of *When Work Disappears*, a book that contains far more detailed discussion of social policy than Wilson's previous ones. The critics of *When Work Disappears* tended to fall into one of two camps: those who felt that somehow Wilson had abandoned his own community and, like Moynihan before him, seemed to put an undue burden on the victims and not enough on the system; and those who, like Greenstein, felt that he was spot-on in terms of the problems but rather naive in terms that, given the political climate, his recommendations could bring about the far-reaching structural changes. Either way, it seemed there was a tendency to 'kill the messenger,' the messenger being Wilson himself.

Among those who most closely examined the Wilson's writings up to and including the publication of *When Work Disappear*s is the sociologist Jack Niemonen. In a book-length study called *Race, Class, and the State in Contemporary Sociology: The William Julius Wilson Debates* (2010), Niemonen examined a number of issues that appear and reappear throughout the body of Wilson's scholarly oeuvre, most but not all still focused on 'The Race–Class Debate.'

Perhaps Niemonen's most critical chapter reflects the sentiments many had long expressed. He called it "Wilson's Achilles Heel," that is, Wilson's seeming failure to adequately come to terms with the continuing significance of racially-based segregation. His charge reprises the negative reaction of the Association of Black Sociologists way back in 1978, the year he was awarded the American Sociological Association's Sydney Spivack Award "for recognition of a significant sociological work in intergroup relations over the previous five-year

period." It is a matter that, as already noted, is a leitmotif in the writings of those who dismiss his basic premises.

Niemonen's own conclusion seemed to damn Wilson with faint praise. Like Greenstein and others, he starts by acknowledging the important role that Wilson played in catalyzing a reassessment of the relationship of race and class, and a renaissance of theoretical constructs related to social stratification in general – something that was already being done by several sociologists. Niemonen allows that Wilson's early writing, particularly the principal thesis in *The Declining Significance of Race*, not only led to a number of studies to test it, including those extensive surveys by Wilson's teams, but also to Wilson's modification of it in subsequent essays and in later editions of the book that started the whole debate:

> Without a doubt, Wilson's contribution to the sociology of race relations ranks as extraordinary and productive. Nevertheless, I have to conclude that his attempt to bridge the racial divide through affirmative opportunity and economic growth falls short. An explicit recognition of the state's role in structuring life-chances in the industrial and modern industrial periods is missing.

But Wilson does this. Whether emphasizing continuing discrimination against African-Americans that makes it even harder for them to compete or broader societal changes related to the shifting demands of the economy, excessive power of large corporations and legislative logjams caused by bittern political polarization which contribute to difficulties not only for the never-hads but also for the once-hads, he has long argued for innovative programs and much greater government intervention. He has also been quite specific about the areas most in need of such assistance.

The gnawing question seems not to be the inappropriateness of Wilson's solutions relating to employment and education, but a conundrum faced by people like Neimonen – and himself – who understand the problems and have concrete solutions but find implementation of truly effective societal-changing policies difficult owing to the fact that public support and funding are dependent on the willingness of those who govern to commit themselves to making dramatic structural changes. At the present time, the prospect of such happening is highly unlikely.

More Recent Work

"Well, there goes the neighborhood!" is a sardonic expression long associated with urban succession often said to be caused by the invasion of "others" (Irish, Italians, Jews, Latinos, Asians, and especially African-Americans) who are perceived as threats to a way of life and to property values. Wilson and a group of colleagues set forth to examine the veracity of the phrase in four sections of Chicago, each an ethnic enclave. The study resulted in another book, *There Goes the Neighborhood: Race, Ethnic, and Class Tensions in Four Chicago Neighborhoods and Their Meaning for America*, written with Richard Taub and based on the research of several teams of graduate students and assistants. Published by Alfred A. Knopf in 2006, it offers a twenty-first century reprise of the type of sociological research conducted by those in the Chicago School under the leadership of Robert E. Park in the 1920s and 1930s. As was the case nearly a century ago, the focus was on different communities; now, as then, the emphasis is on stability and change. *There Goes the Neighborhood* also offers personal commentaries and rich statistical data that provides ample evidence – some quite startling, of persisting prejudices and considerable defensive insulation in the four working- and lower-middle class neighborhoods mainly inhabited by whites, blacks, Latinos, and others, respectively. This major study of Chicago today reminds the reader of the seminal line in Nathan Glazer and Daniel Patrick Moynihan's 50-year-old book about New York City, *Beyond the Melting Pot*, when the authors bluntly stated, "The point about the melting pot … is that it did not happen. At least not in New York and, *mutatis mutandis*, in those parts of America which resemble New York."

From the researches and reflection of William Julius Wilson and his colleagues, today's Chicago resembles New York of the 1950s in many significant ways. And, in words first used by the sociologist, Milton M. Gordon, in *Assimilation in American Life* (1964), structural assimilation, especially among those in the working-class in American cities is still a long way off.

There Goes the Neighborhood provided important insight in many of the matters on which William Julius Wilson had been drawn to examine over the years. This is again reflected in his most recent book, which, in itself, ties together many loose ends.

More Than Just Race: Being Black and Poor in the Inner City, published by Norton in 2009, part of a series of volumes under the editorship of Wilson's Harvard colleague, Henry Louis Gates, is a brief but surprisingly comprehensive portrait of urban sociology and anthropology, most of it focused on studies and theories about social conditions in the inner city in post–World War II America. The major emphasis is on the inequities built into the social structure that exacerbate cultural styles and responses on the part of those in both the dominant groups and in the minorities, especially blacks.

The Legacy of William Julius Wilson

Like the late historian, Stanley M. Elkins, author of *Slavery: A Problem in American Institutional and Intellectual Life* (1959), and the late Senator Daniel Patrick Moynihan, author of many books and reports, not the least, *The Negro Family: A Case for National Action* (1964), William Julius Wilson has often found himself in the middle of disputes about his contentions – and his intentions, his research, his analyses, and his use of the term 'underclass' as a shorthand expression for the urban poor. (One of the best examples of his explication of the concept and an explanation of the word as an appropriate one for that on which he was so keenly focused appeared in "The Underclass: Issues, Perspectives, and Public Policy" in a special issue of the *Annals of the American Academy of Political and Social Science* in January 1989.)

Controversies about his work often motivated Wilson to rethink certain suppositions and declamations. And he did. Sometimes he modified positions taken, more often he qualified them, countering challengers with compelling arguments, often presenting solid empirical evidence to back his claims. In

reference to a late edition of *The Declining Significance of Race* in a *New York Times* book review several years ago, the sociologist Paul Starr called it "easily one of the most erudite and sober diagnoses of the American black situation. Students of race relations and anybody in the policy-making position cannot afford to bypass this study." Nor, it should be added, should they overlook William Julius Wilson's other work, all elaborations, refinements, and variations on his basic theme.

Thoughtful, thorough, and innovative, it is not without reason that this mild-mannered man with a steely mind is seen by many as the very model of a modern sociologist, traits that have led to his garnering of many honorary doctorates, fellowships including a coveted MacArthur 'genius award,' invitations to lecture at hundreds of colleges and universities, and invitations to serve on innumerable boards and panels relating to his principal concerns.

A major theme in the domestic agenda of the second term of American President Barack Obama was to address social inequality, urban poverty, and the growing rifts not only within the black community but throughout the United States. These are the very issues that have long been and remain at the very core of William Julius Wilson's research and analyses, and his repeated calls urging action be taken to enhance access to the mainstream of society for those most disadvantaged by structural and cultural factors.

Abstract

Psychological wisdom research is a relatively young and fast-growing field. This article first gives an overview of the history of psychological wisdom research and work on laypeople's theories of wisdom. Then, psychological conceptions of wisdom are reviewed, and approaches to measuring wisdom are described. The relationships of wisdom to age, including developmental theories of wisdom, and to other psychological constructs such as intelligence and personality are reviewed, followed by approaches to fostering wisdom in the short and long run. Finally, new developments and important open questions are discussed.

Introduction

Ever since human beings began to reflect upon themselves and life in general, they have arguably been striving for wisdom – for ways to deal with the fundamental questions of being human, such as our awareness of our own mortality, and for understanding what it means to live a good life. Long before the science of psychology entered the stage, the Greek term 'philosophia' was coined to describe people's longing and search for wisdom, and questions of wisdom have been central not only to the philosophical, but also the religious sciences and other fields of the humanities for a long time (cf Curnow, 1999; Osbeck and Robinson, 2005).

Within psychology, wisdom has become a major topic only recently. Some early classics in the life-span developmental literature (e.g., Erikson, 1959; Hall, 1922) discussed wisdom as an ideal late-life outcome, but empirical wisdom research did not really begin before the 1980s. Then, wisdom research grew slowly in the context of a general trend toward differentiated conceptions of aging, but remained limited to a very small number of research groups until about 2000. In recent years, the number of theoretical conceptualizations, empirical research approaches, and fields of application has steeply increased, and currently wisdom is being investigated in many different contexts and research traditions. This interest in wisdom is probably related to social, political, and demographical developments that create broad concerns for issues of positive aging as well as for general societal and ethical questions of how human lives should be lived.

Lay Theories of Wisdom

To get a first grasp of the multifaceted and somewhat elusive concept of wisdom, early psychological wisdom research investigated laypeople's conceptions (e.g., Clayton and Birren, 1980; Sternberg, 1985; overview in Bluck and Glück, 2005). Lay conceptions are often referred to as 'implicit theories' of wisdom (Sternberg, 1985), although the methods used to investigate them tend to be rather explicit, using, for example, lists of characteristics that laypeople rate concerning their centrality for wisdom. This research derived some core components of wisdom that were also important in shaping psychologists' emerging theories. For example, Clayton and Birren (1980) identified a cognitive, reflective, and affective component of wisdom – a structure that is still seminal to psychological conceptions of wisdom (Ardelt, 2003).

Later research on lay theories mostly focused on individual differences in wisdom conceptions, e.g., across cultures (Takahashi and Overton, 2005; Yang, 2001) or age groups (Glück and Bluck, 2011). One main distinction is between cognition-oriented, analytical conceptions of wisdom that focus on life knowledge and complex thinking and more integrative conceptions that include noncognitive characteristics such as concern for others. Cross-cultural research has found that typical 'Western' conceptions of wisdom tend to emphasize cognition, whereas 'Eastern' conceptions include noncognitive aspects such as humility, empathy, and emotion regulation as equally central (Takahashi and Overton, 2005). While these differences reflect general tendencies across cultures, there are also individual differences within cultures. For example, middle-aged and older adults view affective aspects as more central to wisdom than young adults do (Glück and Bluck, 2011).

Psychological Definitions of Wisdom

With the growing number of researchers in the field, the number of definitions and operationalizations of wisdom is also increasing, with different approaches emphasizing different aspects. In the following, four current approaches are described in some detail; **Table 1** gives an overview of a larger number of conceptions.

The Three-Dimensional Wisdom Model

Monika Ardelt's Three-Dimensional Wisdom Model (Ardelt, 2003) defines wisdom as a personality characteristic that consists of three components. The cognitive component is based on the motivation and ability to understand the human condition and its core issues, especially intra- and interpersonal matters. This motivation leads individuals to acquire rich and deep factual and procedural knowledge. The reflective

Table 1 Overview of current definitions of wisdom

Authors	*Definition of wisdom*
Ardelt (2003)	Integration of cognitive (ability to understand life), reflective (taking many different perspectives), and affective (positive emotions and behavior toward others) dimensions.
Baltes and Staudinger (2000)	Expertise in the fundamental pragmatics of life entailing factual knowledge, procedural knowledge, life-span contextualism, value relativism, and acceptance and management of uncertainty.
Brown (2004)	Wisdom develops through the interaction of an orientation towards learning, relevant experiences, and interactions with others. These three factors lead the individual to learn from life, that is, to reflect and integrate experiences and apply what has been learned.
Brugman (2006)	Eudaimonic life in the face of uncertainty, involving (meta-)cognition (acknowledging uncertainty), personality and affect (emotional stability despite uncertainty), and behavior (ability to act in the face of uncertainty).
Glück and Bluck (2013)	Affective, self-related, and cognitive integrity acquired through the interaction of life experiences with four resources (openness, reflectivity, emotion regulation, and sense of mastery).
Brown and Greene (2006)	Self-knowledge, understanding of others, judgment, life knowledge, life skills, and willingness to learn.
Grossmann et al. (2010)	Six criteria for wise reasoning: perspective-shifting to take different viewpoints, recognition of the likelihood of change, flexibility of predictions, recognition of uncertainty and the limits of knowledge, search for conflict resolution, and search for compromise.
Jeste et al. (2010)	Six components of wisdom common to published definitions: prosocial attitudes/behaviors, social decision-making/pragmatic knowledge of life, emotional homeostasis, reflection/self-understanding, value relativism/tolerance, acknowledgement of and dealing effectively with uncertainty/ambiguity.
Knight and Laidlaw (2009)	Result of a self-concept and life narrative that incorporates lifespan contextualism, accumulated life experience ('knowing how'), tolerance of uncertainty, and a balancing of dialectics such as emotion and reason.
Levenson et al. (2005)	Self-transcendence, building on self-knowledge, non-attachment, and integration.
Mickler and Staudinger (2008)	Realizing one's own potential while considering the well-being of others and society, combining rich self-knowledge, heuristics of growth and self-regulation, interrelating the self, self-relativism, and tolerance of ambiguity.
Sternberg (2007)	Use of successful intelligence, creativity, and knowledge as mediated by values to seek to reach a common good by balancing inter-, intra-, and extrapersonal interests in a short- and long-term perspective by adapting to, shaping, and selecting environments.
Webster (2007)	Drawing upon life experience to facilitate the optimal development of oneself and others, entailing life experience, emotion regulation, reminiscence/reflectiveness, openness, and humor.
Yang (2008)	Integration (of ideas, interests, modes, of operation, and personality traits that are ordinarily considered as separate or conflicting), embodiment (taking action to realize one's ideals), and accomplishing positive effects brought forth by acting to the acting self and to others.

component is defined as a general willingness to look at phenomena from different sides and take multiple perspectives. Wise individuals also take different perspectives on themselves, which fosters self-criticism and self-insight. The affective component is defined as an empathetic, caring attitude toward others that extends beyond friends and family to include humankind and the world at large. Together, these three components characterize individuals who are highly interested in learning and growing from experiences and interactions and in improving not just their personal situation but the world at large. Such individuals become sources of knowledge and support for others and live rich, satisfactory lives (Ardelt, 2011a).

Wisdom as Self-Transcendence

Michael R. Levenson (Levenson et al., 2005) argues that the core of wisdom is self-transcendence. A self-transcendent individual is independent of external self-definitions and therefore able to perceive others and the world as they really are, without a need for self-enhancement or self-confirmation. Therefore, self-transcendence encompasses caring relationships and feelings of union with others. Drawing on Trevor Curnow's (1999) philosophical work on culturally universal characteristics of wisdom, Levenson argues that self-transcendence develops through three stages. Self-knowledge is a clear awareness of the internal and external sources of one's self. Detachment is an awareness of the transience and provisional nature of external sources. Integration is the acceptance and inclusion of all self-aspects, overcoming self-illusions, and accepting one's own weaknesses. Individuals who are able to integrate and accept their desirable as well as undesirable sides and the independence of this inner core from external rewards are able to develop self-transcendent relations to others and the world.

The Berlin Wisdom Model

The Berlin Wisdom Model, developed by Paul Baltes and colleagues from the 1980s on (overview in Baltes and Staudinger, 2000), was for a long time the sole 'gold standard' in conceptualizing and measuring wisdom. It defines wisdom as expertise in the fundamental pragmatics of human life: just as some people become experts in mathematics or chess, the model assumes that some individuals are motivated to learn about what it means to be human and how to deal with the difficult, existential issues of life. Through reflecting upon direct and indirect experiences with such issues, they develop wisdom-related knowledge, which is characterized by five criteria. Factual knowledge is knowledge of the nature and variability of personalities, developmental trajectories, and relationships. Procedural knowledge includes general and

specific strategies and heuristics for dealing with one's own and others' life problems. Life-span contextualism means awareness and consideration of the fact that people's views and behavior are strongly influenced by contextual factors and developmental stages. Value relativism is awareness and acceptance of individual and cultural differences in value orientations. Perhaps most importantly, recognition and management of uncertainty means an awareness of the inherent unpredictability and uncontrollability of human life and the ability to deal with it.

Wisdom as Self-Distanced Reasoning

Igor Grossmann and colleagues have recently developed a new approach to investigate wise reasoning. They define it as "the use of certain types of pragmatic reasoning to navigate important challenges of social life" (Grossmann et al., 2010, p. 7246). These types of pragmatic reasoning involve dialectical thinking and intellectual humility and manifest themselves in the ability to take different viewpoints, recognize the limitations of knowledge and the likelihood of change, make flexible predictions, and search for conflict resolution and compromise. Grossmann et al. (2010) showed that these indicators increase with age for reasoning about group conflicts and increase or stay stable for reasoning about individual conflicts. Grossmann et al. (2013) found that wise reasoning, but not intelligence, is associated with various indicators of well-being and even with longevity.

Grouping Definitions of Wisdom

The four models described above emphasize different aspects of wisdom. While Ardelt and Levenson consider wisdom as a mature stage of personality development characterized by self-reflection and self-transcendence, the Berlin model and Grossmann's approach emphasize wise forms of thinking and life knowledge. As other conceptions can be categorized along similar lines, Staudinger et al. (2005) suggested to distinguish conceptions of 'personal wisdom,' which is acquired through personal life experiences and concerns one's own life, from conceptions of 'general wisdom,' which pertains to human life in general. The existing psychological definitions of wisdom can be grouped into these two categories quite neatly (see also Staudinger and Glück, 2011). However, personal and general wisdom may also reflect different perspectives on the same phenomenon: perhaps a self-reflective way of perceiving and thinking about experiences leads individuals to develop self-transcendence and concern for others as well as certain types of general knowledge and ways of thinking (Ardelt, 2003).

Table 1 lists current psychological definitions of wisdom and their components, illustrating the commonalities and differences among the conceptions. Some commonalities at least across the majority of definitions are the following. (1) Wisdom is a quality that manifests itself in challenging situations of human life, such as interpersonal and intrapersonal conflicts, confrontation with mortality, and difficult decisions. (2) Wisdom includes a broad and deep body of knowledge, obtained through direct and indirect experience. (3) Wisdom encompasses an awareness of the multiplicity of perspectives and the uncertainty of outcomes. (4) Wisdom includes an orientation toward a larger common good. Wisdom researchers differ in how much importance they assign to these aspects, particularly (just like laypeople) with respect to concern for a larger common good, which is central to some wisdom definitions but not included at all in others.

Measuring Wisdom

The differences in definitions of wisdom could be considered largely as a matter of emphasis, but they have resulted in marked differences in how wisdom is measured. Wisdom definitions that center on reflective or affective aspects have mostly been translated into self-report scales, whereas cognition-centered definitions have generated performance measures. An overview of the most common measures is given in the following.

Self-Report Scales

A number of self-report wisdom scales have been developed and tested for reliability and validity. These include the 39-item Three-Dimensional Wisdom Scale (3D-WS; Ardelt, 2003), which measures Ardelt's cognitive, reflective, and affective dimension. The Self-Assessed Wisdom Scale (SAWS; Webster, 2007) consists of 40 items measuring openness, emotional regulation, humor, critical life experience, and reminiscence and reflectiveness. The Adult Self-Transcendence Inventory (ASTI; Levenson et al., 2005) measures wisdom as self-transcendence. The most current version consists of 34 items, 10 measuring alienation and 24 measuring self-transcendence. The Wisdom Development Scale (WDS; Brown and Greene, 2006) consists of 79 items measuring eight components: self-knowledge, altruism, leadership, judgment, life knowledge, life skills, emotional management, and willingness to learn. The 20-item Brief Wisdom Screening Scale (Glück et al., 2013) was empirically derived by selecting those items from the 3D-WS, ASTI, and SAWS that had the highest loadings on a common factor.

Advantages and Disadvantages of Self-Report Scales

The clear advantage of self-report wisdom scales is that they are easy to administer and score. The main potential problem is that participants may distort responses intentionally or unintentionally. While this is true for all self-report assessments of positive constructs, it may be particularly problematic with wisdom because wisdom entails critical self-reflection: truly wise individuals may describe themselves less positively than people with strong self-illusions. Using reverse-coded items, as is the case in the 3D-WS, may alleviate the problem, but may also have negative effects on reliability and increase cognitive load. Correlations to social desirability have been found for the 3D-WS and the SAWS (Ardelt, 2003, 2011b; Taylor et al., 2011).

Performance Measures of Wisdom

The face-validity issues with self-report scales suggest the use of performance tasks. Participants are presented with open-ended

problems that tap wisdom-related competencies, and their responses are rated with respect to wisdom-related criteria. The most prominent performance measure is certainly the Berlin Wisdom Paradigm (overview in Baltes and Staudinger, 2000). Participants are presented with brief descriptions of difficult life problems such as "A 15-year-old girl wants to move out of her family home right away" or "In reflecting over their life, people sometimes realize that they have not achieved what they had once wanted to achieve." They are asked to think aloud about what could be considered and done in such a situation. Responses are transcribed and rated with respect to five criteria: factual knowledge, procedural knowledge, life-span contextualism, value relativism, and recognition and management of uncertainty.

A performance measure of personal wisdom was developed by Mickler and Staudinger (2008). The *Bremen Wisdom Paradigm (BrW)* is in many respects parallel to the Berlin Wisdom Paradigm, but it focuses on the wisdom that participants have developed with respect to their own self and life experiences. Participants are asked to think aloud about themselves as a friend, including their behavior in difficult situations, reasons for their behavior, and their strengths and weaknesses. Responses are transcribed and rated with respect to five criteria: rich self-knowledge, heuristics of growth and self-regulation, interrelating the self, self-relativism, and tolerance of ambiguity.

Grossmann et al. (2010) developed a new paradigm for measuring wise reasoning. Participants are presented with stories about conflicts between social groups, such as ethnic tensions or the assimilation of immigrants, in foreign countries. They are interviewed about what they think will happen in those countries and why. Response transcripts are coded for perspective-shifting to take different viewpoints, recognition of the likelihood of change, flexibility of predictions, recognition of uncertainty and the limits of knowledge, search for conflict resolution, and search for compromise.

Advantages and Disadvantages of Performance Measures

All performance measures that are currently available consist of open-ended tasks, which mean that they require high efforts for transcription and coding. Attempts to develop closed-ended questions have been unsuccessful to date, probably because it is far easier to recognize than to produce a wise solution to a problem.

A potential problem with performance measures is that they may overemphasize cognitive aspects of wisdom: giving a wise response to a theoretical problem faced by a fictitious person may require wisdom-related knowledge, but it may not tap aspects of self-reflection, emotion regulation, and empathy that the same problem would require if it occurred in real life (Ardelt, 2004). Some new approaches to measuring wisdom try to increase participants' self-immersion in different ways; for example, by using videos of real conflicts (Thomas and Kunzmann, 2013) or autobiographical narratives (Glück et al., 2005). Other possibilities are to include the perspective of other persons by studying wisdom nominees (Ardelt, 2003; Baltes et al., 1995; Glück et al., 2013; Yang, 2011) or to collect peer ratings of wisdom (Redzanowski and Glück, 2013).

Relations of Wisdom to Other Variables

In the following, the relationships of wisdom to relevant psychological variables (intelligence, personality, affect and well-being, and identity-related constructs) and chronological age are reviewed.

Psychological Correlates of Wisdom

Table 2 summarizes findings about correlations of measures of wisdom to four groups of variables: intelligence, personality, affect and well-being, and identity-related constructs. Some of the constructs are conceptually so close to wisdom that they are components in some conceptions of wisdom but treated as correlates by others. For example, Webster's SAWS (Webster, 2007) includes subscales named 'openness to experience' and 'emotional regulation.'

As **Table 2** shows, the correlations between measures of wisdom and intelligence tend to be relatively low. They are somewhat higher for performance-based measures of wisdom, which may be partly due to shared method variance. Conceptually, one would expect to find positive correlations between wisdom and crystallized intelligence and no or negative correlations between wisdom and fluid intelligence, but the empirical findings only partly support this assumption. While the SAWS and Grossmann's wise reasoning measure show the expected pattern of correlations, the 3D-WS, BWP, and BrWP are positively related to fluid intelligence. It is an open question, however, whether linear correlations are a good measure for the relations of wisdom to other variables. For example, wisdom might require a certain minimum level of intelligence but be unrelated to intelligence above that level.

With respect to personality, the one Big Five dimension that has turned out to be related to wisdom in almost all studies is openness to experience. People higher in openness are more likely both to encounter new ideas, experiences, and contexts, and to learn and grow from them throughout their life. Apart from openness, there is a clear divergence between self-report measures of wisdom, which tend to be correlated to various personality dimensions, and performance measures, which are mostly uncorrelated to personality. This may be the case partly because most self-report measures are based on conceptions of wisdom that include personality aspects and partly due to shared method variance, as all studies listed in **Table 2** measured personality by self-report.

There is an ongoing controversy about the relationship between wisdom and well-being. While some authors argue that wisdom is closely related to life satisfaction and positive affect (e.g., Ardelt, 2011a), others believe that wisdom entails an awareness of the difficult and negative sides of human life that may prohibit high levels of happiness (Kunzmann and Baltes, 2003; Staudinger and Glück, 2011). Conceptually and empirically, wisdom is clearly more closely related to eudaimonic well-being, the awareness of meaning in one's own life, than to hedonic well-being, the simple enjoyment of a pleasurable life (Kunzmann and Baltes, 2003; Le, 2011; Webster et al., 2013).

Relationships to identity-related and experiential variables tend to be relatively low but consistently positive across measures of wisdom: wisdom is related to higher levels of

Table 2 Correlations of measures of wisdom to other psychological constructs

identity development, as manifested in variables such as ego development, integrity, and generativity, and in an orientation toward personal growth and learning. Interestingly, correlations between life experiences and wisdom have not been investigated very often, but they tend to be low to insignificant. These findings support the notion that wisdom is not fostered by any particular experiences per se but by the way individuals deal with them, reflect upon them and their own role in them, and integrate them into their life story (Glück and Bluck, 2013).

Wisdom and Age

How is wisdom related to age? Laypeople (Bluck and Glück, 2005; Glück and Bluck, 2011) and wisdom researchers (Jeste et al., 2010; Staudinger, 1999) seem to agree in two points: First, wise people tend to be old rather than young, but second, wisdom does not generally come with age. These two seemingly contradictory statements can be reconciled by assuming that wisdom is a relatively rare phenomenon that emerges in only a small number of individuals – those who have the necessary cognitive, affective, and motivational resources and encounter contexts and experiences that foster learning and growth. Empirically, relations to age differ across measures of wisdom. The Berlin Wisdom Paradigm is unrelated to chronological age in adulthood (Staudinger, 1999; Pasupathi et al., 2001). Grossmann's measure of wise reasoning (Grossmann et al., 2010) is positively related to age, whereas the Bremen Personal-Wisdom Paradigm and the 3D-WS are negatively related to age. It may be worthwhile to also look for nonlinear relations, as recent work has found an inverse U-shaped relation of the SAWS with age (Webster et al., 2013). How a particular measure is related to age probably depends on which facets of wisdom it emphasizes. While some aspects, such as relativistic thinking, affective positivity, or accumulated life experience may increase with age, others, such as fluid intelligence or self-concept complexity, decrease in older age. Wisdom is a relatively rare optimal constellation of these facets, which implies that wise individuals may be able to compensate losses in some domains better than other people do. For example, the idea of wisdom as expertise suggests that the development of wisdom involves the acquisition of strategies and heuristics that can overcome cognitive limitations resulting from losses in fluid intelligence in old age.

Theories of the Development of Wisdom

Why do a few individuals develop high levels of wisdom in the course of their lives, while so many others, faced with similar experiences, do not seem to learn or grow from them? The fact that high levels of wisdom are rare suggests that the development of wisdom requires specific constellations of resources and experiences. In the context of the Berlin Wisdom Paradigm, Baltes and Staudinger (2000) suggested that the development of wisdom involves characteristics of the individual such as intelligence, creativity, or openness to experience; expertise-specific factors such as the availability of mentors or a motivational disposition to strive for wisdom; and relevant experiential contexts such as parenthood, certain professional roles, or old age.

Somewhat more specifically, the MORE Life Experience Model of the development of wisdom (Glück and Bluck, 2013) proposes that wisdom develops through an interaction of psychological resources with challenging life experiences. The four most relevant resources are Mastery, Openness, Reflectivity, and Emotion Regulation/Empathy (MORE). They influence what life challenges people encounter and how they appraise them, how they deal with challenges, and how they integrate past challenges in their life story. Individuals who are higher in the MORE resources are more likely to deal with a life-changing experience in a way that fosters both the resources themselves and learning and growth toward wisdom.

Fostering Wisdom

How can individual and societal wisdom be fostered? This question has obvious societal relevance. Psychological work suggests that it is indeed possible ways to enhance wisdom by targeted interventions. Two different lines of theoretical and empirical work focus on long-term and short-term interventions. Long-term interventions are mostly discussed with respect to educational systems: are there ways in which schools or universities could teach for wisdom (Brown, 2004; Ferrari and Potworowski, 2008; Sternberg, 2001)? Although little empirical research has been published, it seems likely that especially cognitive facets of wisdom, such as relativistic thinking and critical self-reflection, can be practiced in educational settings.

Another kind of long-term intervention that may foster wisdom is psychotherapy. Generally, it could be argued that any psychotherapy aims at improving wisdom-related capacities such as self-reflection, emotion regulation, and empathy, and it would certainly be worthwhile to investigate the effects of psychotherapy on wisdom. More specifically, a 'wisdom therapy' has been developed for treating embittered participants (Linden et al., 2011). Based largely on the Berlin wisdom model, this approach focuses on a cognitive reframing of the life experiences that caused embitterment by taking different perspectives and roles and considering different persons, contexts, and values.

Short-term wisdom interventions have been investigated experimentally both by the Berlin wisdom group and by Igor Grossmann and colleagues. All wisdom interventions that have proven successful to date instructed participants to transcend their own viewpoints: Wisdom-related knowledge can be fostered by imagining to discuss the task with a close other person (Staudinger and Baltes, 1996), as well as by taking a distanced rather than self-immersed perspective on an issue (Kross and Grossmann, 2012). Interestingly, an instruction to "try to give a wise response" elicited higher levels of wisdom-related knowledge only in participants who were relatively wise to begin with (Glück and Baltes, 2006).

These findings also imply a certain degree of state-dependence of wisdom: if a simple instruction is sufficient to elicit higher levels of wisdom in people than they usually show, the question arises to what degree situational contexts in general are conducive or obstructive to wisdom. For example, high emotional involvement in a situation may have negative effects on wisdom.

Current Developments and Important Next Steps

Current developments of wisdom research take two different directions. On the one hand, wisdom research is applied in societally relevant contexts such as leadership or medical ethics. On the other hand, the conceptions and paradigms of genuine wisdom research are currently expanding in several new directions.

The Societal Relevance of Wisdom Research

When laypeople are asked to nominate wise figures, many nominees (e.g., Mahatma Gandhi, Jesus Christ, Martin Luther King, or Nelson Mandela; Paulhus et al., 2002) fit into our idea of 'leaders,' that is, they have inspired millions of followers and improved the lives of people fundamentally. In this vein, it has been argued that wisdom is a crucially important characteristic of economical and political leaders, although for the time being, there is more theoretical than empirical work on wise leadership (e.g., Kilburg, 2006; McKenna et al., 2009; Sternberg, 2007; Yang, 2011). However, the idea that if only politicians and managers were wiser, the world would be a better place may be too simple. For example, the wisdom of managers is not independent of organizational culture (Limas and Hansson, 2004). The goals and structural requirements of leading a state or a big company may not or only partly be compatible with characteristics of wisdom such as striving for a common good rather than maximizing profit (Staudinger and Glück, 2011).

Wisdom has also been investigated in the context of medical ethics, which touches upon some of the fundamental issues of human existence. For example, Barilan (2009) argues that a critical and reflective moral attitude contributes to wise decisions in the context of truth-telling to terminally ill patients. Kaldijan (2010) discusses wise clinical judgment on the basis of philosophical conceptions of practical wisdom.

New Developments in Psychological Wisdom Research

As mentioned before, psychological wisdom research is a fast-growing field. New paradigms are developed for measuring wisdom (e.g., Grossmann et al., 2010; Redzanowski and Glück, 2013; Thomas and Kunzmann, 2013), fostering wisdom (e.g., Kross and Grossmann, 2012; Linden et al., 2011), and analyzing data beyond linear correlations (e.g., Webster et al., 2013). We are learning more about the development of wisdom (e.g., Glück and Bluck, 2013; Thomas and Kunzmann, 2014). Still, a large number of important questions are still open. First, most research has been conducted in modern Western societies – which aspects of our conceptions of wisdom are universal, and which are dependent on cultural, historical, and societal contexts? Second, while intraindividual predictors of wisdom such as personality or intelligence are well-studied, little research has investigated the role of social and societal resources for the development and manifestation of wisdom. Third, how can wisdom be measured in more ecologically valid ways? We hope that these questions and many others will be tackled by the wisdom researchers of the next decades.

Wisdom: Philosophical Aspects

Wolfgang Welsch, Friedrich Schiller University, Jena, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The first part of the article retraces shifts in the understanding of wisdom from antiquity to modern times. Having originally, as with the Seven Sages of Greece, betokened practical–political expertise, 'wisdom' for Plato became a specifically theoretical notion, and for Aristotle the highest praxis as philosophy. In Hellenistic and Roman philosophy, the sage was once again conceived of as an expert in practical matters of human life. In modern times, when philosophy came to be associated increasingly with science, wisdom still remained important on the practical side but was also criticized more and more. The second part of the article focuses on a contemporary understanding of wisdom. It is shown that particularly concepts in recent theoretical – not practical – discourse exhibit traits fruitful for wisdom. Nietzsche, Quine, and Wittgenstein, among others provide elements suitable for a new, epistemologically inspired, understanding of wisdom centered around circumspection, awareness of plurality, limits of justification, and competence in dealing with uncertainty. From this a renewal of philosophy's role as a powerful source of wisdom could result.

Wisdom is not a central topic of contemporary philosophy. Today's philosophers seem to confirm Nietzsche's observation: "When philosophers meet among themselves they start casting off all sorts of wonderful rubbish; above all … they hang up 'the love of wisdom' like stuffy robes of office" (Nietzsche, 1980a: p. 511). Common sense, on the contrary, still expects wisdom to be provided by philosophy, and the discipline's social reputation is partly based on this expectation. But as contemporary philosophy seems scarcely inclined or able to fulfill this demand, common sense draws on forms of wisdom from nonoccidental cultures or from esoterics. While 'wisdom' is a term rarely used in contemporary philosophy, the literature about wisdom from the esoteric and the anthropological–cultural side is flourishing.

There is nothing wrong with sensing deficiencies in the academic field and turning to other sources instead. Yet in the second part of this article, it will be demonstrated that contemporary philosophy can in fact provide a great many elements of wisdom appropriate for our times. The first part is devoted to an accurate reconstruction of the main historical turns in the philosophical understanding of wisdom.

Philosophy – A Concept Introduced by Plato

As is commonly known, philosophy is related through its name to wisdom: 'philo-sophy' (in Greek: *philo-sophia*) means 'love of wisdom' or 'quest for wisdom' (in Greek: *sophia*). But this concept of *philosophia* corresponds neither to the original understanding of philosophical thinking nor to that of wisdom. The concept of *philosophia* was first created by Plato in the first half of the fourth century BC.

The Pre-Platonic Understanding of Philosophy and Wisdom

Philosophers before Plato neither deployed the term 'philosophy' nor described their enterprise with respect to wisdom (*sophia*). Rather, they characterized their doctrines as 'histories.' Moreover, the Greek understanding of wisdom – as paradigmatically expressed in the topical talk of the 'Seven Sages of Greece' – focused on practical, not theoretical knowledge. In everyday language, a wise person was just an expert of some kind or other (a craftsman, artist, doctor, military leader, etc.); in order to be included in the catalog of the Seven Sages his work had, in addition, to be of extraordinary political relevance. So Thales, the only ancient philosopher ever to figure among the Seven Sages, was included in this group not as a philosopher, but as an astronomer and engineer who brought military success to his community by predicting an eclipse and redirecting a river.

Plato's Turn

What, then, is the specific sense of Plato's introduction of the concept of *philo-sophia* – an innovation so successful that his concept is commonly taken to be *the* concept of philosophy altogether?

Three shifts are characteristic. First, the emphasis in the understanding of *sophia* as well as *philosophia* is put on theory instead of praxis. Philosophers observe the nature of things not for the sake of practical usage but for that of pure cognition. The new concept of philosophy is strictly opposed to the old practical aims of *sophia*. Second, a border line is drawn between philosophy and wisdom: philosophers can only *strive* for wisdom – without ever actually reaching wisdom. This is why philosophy is defined as *philo*-sophy (*love* of wisdom), not as wisdom proper (*sophia*). 'Philosophy' implies an element of modesty and limitation. Thirdly, this limitation cannot be overcome – complete wisdom is reserved for the Gods only. By philosophizing we do not surpass philosophy to actual wisdom.

Strategic Implications

Plato's innovation was directed not only against the traditional and the everyday understanding of wisdom but above all against his contemporary competitors, the Sophists. In everyday language at Plato's time – where compositions with 'philo' had

 http://dx.doi.org/10.1016/B978-0-08-097086-8.63094-5

long since become popular – 'philosophizing' (*philosophein*) was a term without any extravagant meaning; it just meant studying, educating oneself, being inclined to reflective activity. So Plato's declaration that wisdom is impossible for humans and reserved to the Gods alone discredited not only the mythical Seven Sages but also his compatriots' devotion to philosophical activity and above all the Sophists, who at the time of Plato roved from city to city offering, for payment, lessons in rhetoric, virtue, poetry, mathematics, music, or astronomy. As their name (*Sophists*) indicates, they were considered to be bearers of wisdom (*sophia*). The idea that they were in fact frauds – Plato was constantly trying to discredit the Sophists as dealers in fake knowledge, and as being the morally and intellectually dubious counterparts of the real philosopher – was the logical result of Plato's redefinition: If wisdom is altogether unattainable for humans, then the Sophists who masquerade as teachers of wisdom, must obviously be frauds.

Philosophy's Claim to Represent True Praxis and Wisdom

The introduction of modesty and limitations in matters of wisdom with the new concept of philosophy was an efficient strategy in distancing the Sophists, but once this was achieved the proponents of the new concept soon turned to more ambitious claims. Philosophy was successively considered capable of representing the utmost fulfillment of both practical and theoretical wisdom.

Philosophical Theory as the Highest Praxis

The move from a practical to a theoretical emphasis was meant as an empowerment of philosophy in matters of true praxis. The traditional concept of praxis, so characteristic of the original understanding of wisdom, was criticized for having in fact provided only a concept of pragmatic utility, one ignoring the very kind of praxis pertaining to the full accomplishment of human life. This higher and true sense of praxis was to be fulfilled precisely by philosophy in the new sense of theoretical activity. This tendency is obvious already in Plato, who always conceived of philosophy as the best way of human life, with respect to both the philosophizing individual and societies complying with philosophical insights. And Aristotle (in his emphatic eulogy of theory in *Nicomachean Ethics* X: pp. 7–9) finally openly declared the theoretical life to be the best and highest form of human praxis and life altogether. Significantly enough, he explained the supremacy of theoretical life by contrasting its self-sufficiency with the purposeful orientation of ordinary practical life: according to him, philosophical theory is the only activity "loved for its own sake; for nothing arises from it apart from the contemplating, while from practical activities we gain more or less apart from the action."

Philosophy as Wisdom Proper

Although Plato had initially declared wisdom to be reserved for the Gods, he made the border between human philosophy and divine wisdom permeable. Ultimately philosophizing should result in a *homoiosis theo*, a "becoming like the divine" (Plato, *Theiatetos*, 176 b 1 f). Aristotle definitely dropped the Platonic reserve. According to him, philosophy and wisdom are one – his appraisal of philosophical *theoria* in *Nicomachean Ethics* is one of *sophia*. In theoretical life, he says, we realize "the divine in our midst" and hence our "true Self." With Aristotle, '*philosophia*' is no longer a modest term inferior to *sophia*. Hegel's phrase that philosophy should "lay aside the title "*love* of knowing" and be *actual* knowing" (Hegel, 1977: p. 3) is Aristotelean in spirit.

Reaccentuating the Practical

Theory's Open Flank

But philosophy's effort to completely absorb the older practical aspects of wisdom has an open flank. In his theoretical attitude the philosopher may well possess the utmost theoretical knowledge – but this is not to possess all kinds of knowledge: genuinely practical insight, ethical knowledge, and situational prudence (*phronesis*) are lacking. And although theory may represent the highest form of praxis, it cannot as such replace all forms of praxis. Hence, specifically practical knowledge – lying outside theoretical *sophia* – requires respect and clarification in addition. This applies all the more, given that practical knowledge is (as, quite properly, Aristotle was the first to demonstrate) of an intrinsically different type from theoretical knowledge. So the new concept of philosophical theory, as impressive as it may be, remains in need of supplementation. Genuinely practical knowledge (which is so decisive for all our everyday orientation) requires a different approach.

Hellenistic and Roman Philosophy: The Return of the Sage as a Practical Expert

Following Greek philosophy's classical period, a return to conceiving the sage as an expert in practical matters took place in Hellenistic and Roman philosophy (with the Epicureans and Stoics). The sage once again became a figure of outstanding practical knowledge and exemplariness, knowing how to lead the best life. From now on wisdom was seen as the archetype of accomplished living. Theoretical capacities were to serve this goal.

This understanding of wisdom prevailed even in modern times. So Montaigne defined the sage as someone who appreciates that "our great and glorious masterpiece is to live appropriately" (Montaigne, 1958: p. 851). Kant too declared that "the teacher of wisdom through doctrine and example," "the practical philosopher," "is the real philosopher" (Kant, 1992: p. 537). Even today, we still expect a wise person to embody the right mode of human living.

Middle Ages

The Christian philosophy of the Middle Ages had trouble with wisdom. In the Bible, the wisdom of this world had been declared to be foolishness before God (*Paul*, 1 *Cor*. 3:19; similar 1 *Cor*. 1:20 and *Romans* 1:22). This position, by consequence, called into question the very possibility of reasonable reflection and hence of Christian philosophy altogether. At the least it imposed severe limitations. Some philosophers tried to settle the conflict by developing the doctrine of 'double truth.' But distrust of purely

human knowledge – be it wisdom, reason, or science – prevailed. Luther was later to renew the accusation that reason is "the devil's whore" (Luther, 1964: p. 164, cf also Luther, 1967: p. 82).

Philosophy in League with Science – Not with Wisdom

In modern times, philosophy's ally has been science, not wisdom. When philosophers, occasionally, do still use the term 'wisdom' what they actually have in mind is science. So Descartes uses 'wisdom' as just another name for the sum total of science (Descartes, 1998: p. 65). Even Kant, though affording wisdom the highest rank, emphasizes that "science … is the narrow gate that leads to the *doctrine of wisdom*" (Kant, 1993: p. 171). Husserl was to resume this modern emphasis on science instead of wisdom by declaring "science has spoken, from now on wisdom has the task of learning" (Husserl, 1965: p. 63).

Modern Philosophy's Practical Intentions

But modern philosophy has a strong practical side too. It comes in two flavors: as technical purposiveness along the lines of science, and as moral–practical orientation taking up older elements of wisdom.

Technical–Practical Side

From the start modern science was addressed to technical ends. It was in this respect that Bacon and Descartes commended it. Marx then claimed that philosophy should become altogether practical – and thus realize itself by vanishing as philosophy. Even if this project has failed, the prospect of technically reshaping reality has proven widely successful.

Moral–Practical Side

Complementary to this scientific–technical strain, to which wisdom is irrelevant, practical aspects of wisdom survive in modern philosophy's other strain, the practical one devoted to ethics and morals. It is here, if anywhere, that 'wisdom' can be a substantial term in modern times. Descartes had already conceived of ethics as "the final stage of wisdom" (Descartes, 1983: p. XXIV), and Kant, having defined wisdom as "the idea of the practical use of reason's complete conformity to law" (Kant, 1983), afforded this practical wisdom the highest rank, declaring "the practical philosopher" to be "the real philosopher" (Kant, 1992: p. 537). In the moral–practical respect wisdom retains the highest esteem.

Enlightenment philosophers, as well as their opponents, agreed that true morality – and by consequence wisdom in its practical sense – is the most important thing for us humans. When Rousseau, in contrast to the 'rationalists,' emphasized the simplicity of moral knowledge, even this claim to simplicity was shared by a great many philosophers of the period. In this they could even see the great advantage of practical over theoretical knowledge: "It took centuries to know part of nature's laws. A single day suffices to recognize man's duties" (Voltaire, 1967: p. 342). With respect to this simplicity distinguishing practical wisdom, Wolff, D'Holbach, and Voltaire proclaimed Confucius, the exemplary 'simple sage,' to have been the wisest person ever.

But obviously this modern line of revalidating practical wisdom was not very fortunate. Why else would we feel disoriented and lament the absence of wisdom appropriate to our times and problems?

Protest against Wisdom – Nietzsche

In the course of time modern philosophers came to protest more and more against all traditional understanding of wisdom. Nietzsche is the most prominent example.

He generally suspected the traditional ideal of wisdom to have been simply a symptom of weakness. The old philosophers' "claim that they possessed wisdom" appears to him to have always been "a screen behind which the philosopher saves himself because he has become weary, old, cold, hard – as a premonition that the end is near, like the prudence animals have before they die: they go off by themselves, become still, choose solitude, hide in caves, and become *wise*" (Nietzsche, 1974: p. 315). The Stoic is the paradigm case for Nietzsche. His wisdom consists in making himself insensible of the tensions of life and acquiring an armor-plated attitude. Hence Nietzsche's ruthless formula: "The stoic type. Or: the perfect ox" (Nietzsche, 1980b: p. 125).

The attitude of the 'genuine philosopher' would, in Nietzsche's opinion, be completely different: he "lives "unphilosophically" and "unwisely," above all imprudently, and feels the burden and the duty of a hundred attempts and temptations of life—he risks himself constantly, he plays the wicked game" (Nietzsche, 1989: p. 125). "The wisest person would be the richest in contradictions, who has, at it were, organs of touch for all kinds of person: and in their midst his great moments of grandiose harmony – in us too the lofty coincidence!" (Nietzsche, 1980a: p. 182).

Ultimately, however, 'wisdom' remains an improper expression in Nietzsche's view – it is too strongly impregnated by its traditional meanings. Only in a critical manner can we still refer to or draw on wisdom. The first possibility is exemplified by Nietzsche's phrase: "There is more reason in your body, than in your best wisdom" (Nietzsche, 1966: p. 146). The second is represented by a striking claim of Nietzsche: "My wisdom has long gathered like a cloud; it is becoming stiller and darker. Thus does every wisdom that is yet to give birth to lightning bolts … For these men of today I do not wish to be light, or to be called light. These I wish to blind. Lightening of my wisdom! put out their eyes!" (Nietzsche, 1966: p. 401).

Languid wisdom or lightning wisdom, wisdom as a sedative or as dynamite – this is Nietzsche's alternative in matters of wisdom. If wisdom is referred to, one should be on one's guard as to which type of wisdom is involved.

Epistemological Contours

Shifting from Practical to Theoretical Philosophy

The disappointment with contemporary philosophy's neglect of wisdom is flawed by one-sidedness. One assumes elements

of wisdom must be found in the field of practical philosophy, where it would indeed be hard to discover any. Conversely, however, insights of contemporary theoretical philosophy provide a great many elements giving contours to a contemporary concept of wisdom. My thesis is that the design of wisdom today is to be drawn from the epistemological development in recent decades.

Recent Insights: Theoretical Reason with the Characteristics of Practical Reason

Shifting to epistemology in matters of contemporary wisdom makes all the more sense given that in recent decades theoretical reason has been shown to be characterized by traits formerly considered typical of practical reason alone. Since Aristotle, the difference between the two types of reason had been considered fundamental: theoretical reason considers permanent things, whereas practical reason deals with changeable things. Correspondingly, theoretical reason demands distance and provides perfect cognition, whereas practical reason requires involvement and allows only context-dependent cognition. In recent decades, however, theoretical reasoning has been shown to bear the same basic traits as practical reasoning: theoretical cognition too represents relative, not absolute cognition; it too is context-bound and its validity is tied to specific (axiomatic, historical, social, etc.) frameworks. In short, theoretical reasoning also exhibits the characteristics of practical reasoning. This explains why the shape of contemporary wisdom can be inferred from innovations on the theoretical side.

Elements of Modern Epistemology Relevant for a Contemporary Concept of Wisdom

As this view is unusual, I will set out in the following sections the relevant elements in some detail.

From Nietzsche to Quine: The Uncertainty of Fundaments

Nietzsche can be regarded as a forerunner of the contemporary condition in having pointed out that our theoretical cognition is of a piece with practical and pragmatic cognition: "one may certainly admire man as a mighty genius of construction, who succeeds in piling up an infinitely complicated dome of concepts upon an unstable foundation, and, as it were, on running water. Of course, in order to be supported by such a foundation, his construction must be like one constructed of spiders' webs: delicate enough to be carried along by the waves, strong enough not to be blown apart by every wind" (Nietzsche, 1979: p. 85). In the twentieth century Neurath said quite similarly, "we are like mariners who must rebuild their ship on the open sea, without ever being able to disassemble it in dock and reassemble it with the best components" (Neurath, 1932–1933: p. 206). Popper's diagnosis reads: "just when we believed that we were standing on firm and safe ground, all things are, in reality, insecure and unstable" (Popper, 1992: p. 65); "the basis is unstable" (Popper, 1969: p. 76). Quine later adopted Neurath's phrase as the motto of *Word and Object* (Quine, 1960: p. VII).

Scientific Pluralism (Quine)

The inevitability of scientific pluralism is a decisive insight of contemporary epistemology that was first formulated by Quine. Even in the strong realm of science, no one, singularly valid theory is to be expected, but a multitude of equally valuable alternative candidates has to be taken into account. This is a consequence of the empirical under-determination of theory shown by Quine in his seminal essay "Two Dogmas of Empiricism" from 1951: "Total science, mathematical and natural and human, is … underdetermined by experience" (Quine, 1980: p. 45). Empirical tests can only tell us that *something* is in need of being altered in the theory, but not exactly *which element* is to be changed. "Any statement can be held true come what may. Conversely, by the same token, no statement is immune to revision" (Quine, 1980: p. 43).

In *Word and Object* (Quine, 1960), Quine resolutely drew the consequences of scientific pluralism: "we have no reason to suppose that man's surface irritations even unto eternity admit of any one systematization that is scientifically better or simpler than all possible others. It seems likelier … that countless alternative theories would be tied for first place" (Quine, 1960: p. 23). "We can never do better than occupy the standpoint of some theory or other, the best we can muster at the time" (Quine, 1960: p. 22).

The Impossibility of Any Meta-Position (an Insight Common to Hermeneutics, Poststructuralism, and Analytic Philosophy)

This also means that it is impossible to assume some meta-position that would allow us to regard the multitude of scientific theories from a superior point of view and select the 'truly right' one among them. There is no God's-eye standpoint, no view from nowhere – neither in theoretical nor in practical matters. The impossibility of such a meta-stance is a decisive insight of recent philosophy that is common to all (superficially so variant) strands: to Gadamer's hermeneutics (according to which we cannot achieve a metahistorical standpoint toward history), to Lyotard's poststructuralism ("Simplifying to the extreme, I define postmodern as incredulity toward meta-narratives," Lyotard, 1984: p. xxiv), and, of course, to analytic philosophy, where this insight was first formulated not by Quine but by Wittgenstein, who declared it his "leading principle" that there is no "metaphilosophy" (Wittgenstein, 1974: p. 116).

Wittgenstein: Limits of Justification

Wittgenstein has developed insights crucial to the present understanding of cognition and also relevant to every conception of contemporary wisdom altogether.

First, Wittgenstein demonstrated limits of justification with respect to the certainties of common sense. These are neither based on cognition nor could they ever be secured by cognitive justification. For these certainties are by themselves constitutive of all our activities of justification: "All testing, all confirmation and disconfirmation of a hypothesis takes place already within a system. And this system is not a more or less arbitrary and doubtful point of departure for all our arguments: no, it belongs to the essence of what we call an argument. The system

is … the element in which arguments have their life" (Wittgenstein, 1972: p. 16).

Second, Wittgenstein showed how this structure affects all our decisions: "Nothing we do can be defended absolutely and finally. But only by reference to something else that is not questioned" (Wittgenstein, 1984: p. 16). Decisions necessarily have recourse to something which they take for granted: "The questions that we raise and our doubts depend on the fact that some propositions are exempt from doubt, are as it were like hinges on which those turn" (Wittgenstein, 1972: p. 44). "If I want the door to turn, the hinges must stay put" (Wittgenstein, 1972: p. 44).

So far this means that not only the validity of scientific theories (Quine), but also of our everyday certainties and all our argumentation, cannot be conclusively secured; they possess only conditional validity. In the regress of justifications one does not reach some incontrovertible ground, but only postulates, which in principle are once again questionable. While admitting good and varied justifiability, there is no such thing as an absolute, ultimate justification.

Finally, Wittgenstein has also shown how all this applies even to the whole framework of justification and argumentation (to 'rationality'): "We can't talk of reasons for thinking … We can describe the game of thinking, but not the reasons why we think. "Reason" only applies within a system of rules … It is nonsense to ask for reasons for the whole system of thought" (Wittgenstein, 1980: p. 88). What Wittgenstein wants to draw our attention to is that the quest for reasons (e.g., for reasons for the whole business of reasoning) suggests leaving behind this game, but obviously it does not do so: it asks the very question that typifies this game itself and thus remains within its realm.

Hence there is no possibility of justification that absolutely vouches for itself. This is expressed in the following sentence (which, significantly enough, sounds like the dictum of a sage): "You must bear in mind that the language-game is so to say something unpredictable. I mean: it is not based on grounds. It is not reasonable (or unreasonable). It is there—like our life" (Wittgenstein, 1972: p. 73).

Epistemic Contemporariness and Wisdom

These epistemic advances, which characterize the present state of affairs in philosophy, surprisingly also correspond to contemporary standards of everyday consciousness. The latter is molded to a high degree by the acknowledgment that all validity is relative and by an awareness of the plurality of modes of experience, cultures, forms of life, and even worlds. Owing to this correspondence, the new epistemic philosophical standards are also apt to serve as maxims for contemporary everyday orientation. They match our expectations and needs in matters of wisdom, and they do so in a manner specifically appropriate to the contemporary situation.

The present understanding of wisdom typically implies circumspection, awareness of limitation, and competence in dealing with uncertainty. The sage is someone who is attentive to neighboring and commonly neglected aspects. She is aware of the context and brings it to bear regulatively. Whereas an ignorant person confidently attributes himself a grasp of the whole, the wise person objects to such totalization. She recognizes the limited nature of all singular perspectives, is aware of differing viewpoints, and attentive to the open potential for additional alternatives. She warns against misrecognizing particularities, infringements, and overbearingness. She advocates justice at the level of detail and openness on the whole. So the wise person is an expert in uncertainty too. Wisdom is particularly needed in situations where justice is required with respect to diverging demands without a meta-rule being available from which one could deduce the right decision. In these cases, even though it be cognized, but only found, the wise person will have a sense for what is right. Sometimes, however, it will be important just to fend off the wrong thing while leaving open what's right. Such composure also distinguishes the wise person.

Contemporary epistemology, which emphasizes the limits of all justification and demands their respect, is thus properly tailored to the aspects of wisdom just set out. It inherently works toward a consciousness that bears traits of wisdom in high measure.

This is why a state of consciousness that has incorporated those epistemic standards and that knows how to practice them can provide orientation for our time and satisfy our demands in matters of wisdom. Whoever has made this genuinely philosophical possibility her own will be in no great need of extra-philosophical and esoteric doctrines of wisdom that have become so popular in recent years.

Witchcraft

Peter Geschiere, University of Amsterdam, The Netherlands

Abstract

Till far into the twentieth century two nodal points in the study of witchcraft stood out: the work by historians on witch trials in early modern Europe, and anthropologists' studies of its role in local tensions in Africa and Melanesia. The differences between the two settings were so glaring that some authors objected to the use of the same term. Yet, in both settings similar themes emerged, even though these were interpreted in quite a different way. Common interests were the relation of witchcraft to the forces of modernity (the State, the Market), but equally its ongoing link to the intimacy of family and home; also its relation to (a)moral power, to healing, and to class differences. Moreover, over the last decades the geography of witchcraft studies was constantly widening: seminal studies appeared concerning different parts of Asia, Latin America, and other regions of the world. In 2004, historian Wolfgang Behringer published a 'global history' of witches and witch-hunts, challenging anthropologists to finally stop their endless bickering over right or wrong terms, so that comparisons could at last take off. The differences between the approaches by historians and anthropologists should not be exaggerated, but precisely the confrontation between the two can help to focus on new directions for research around this challenging topic that seems to refuse to be domesticated.

Until far into the twentieth century, the academic study of witchcraft was concentrated in two research fields clearly separated in time and space: historians' studies of the enigmatic outburst of witches' trials in early modern Europe, and anthropological studies of the role of witchcraft in notably African and Melanesian societies during colonial and post-colonial periods. The contrasts between the historical and anthropological approaches can serve as an entry point for exploring different trends in witchcraft studies in interaction with rapidly changing contexts.

Historians and Anthropologists: Differences and Correspondences in Approach

In her introduction to a conference volume commemorating the 30th year anniversary of Evans-Pritchard's classical study *Witchcraft, Oracles and Magic among the Azande* (southern Sudan), Douglas (1970: p. xiii) noted with some apparent surprise the deep chasm between these two fields of study: "The anthropologists of the 1950s developed insights into the functioning of witch beliefs which seemed about as relevant to the European experience as if they came from another planet. Dangerous in Europe, the same beliefs in Melanesia or Africa appeared to be tame, even domesticated; they served useful functions and were not expected to run amuck." In retrospect, one might wish the second half of this quotation to be still true. People's growing preoccupation over the last decades in many parts of Africa and Melanesia with new forms of witchcraft seems to reflect, on the contrary, widespread worries that it has 'run amuck' in those regions as well.

Yet, Douglas's trenchant observation did highlight striking differences between the trajectories of witchcraft studies by historians and anthropologists and, therefore, offers a challenging starting point for a survey of the topic. The differences between the two fields are, indeed, so great that some authors even objected to the use of the same term. Crick (1979), for instance, warned that the term witchcraft was so saturated with implications stemming from European history that anthropologists working on other areas had better avoid the term altogether. One problem with such a purist stance is that this English term (or the corresponding French, Spanish, and Portuguese words) has been adopted widely by people throughout the Southern Hemisphere. Another consideration might be that despite huge variations the representations concerned revolve around basic conceptions that are surprisingly similar. In many parts of the world notions that are now commonly translated as 'witchcraft' refer not only to hidden human aggression, but also to more specific representations about people being able to double themselves, leaving their bodies at night and flying off to nocturnal meetings with their accomplices.

Especially anthropologists, confronted by a bewildering proliferation of imaginaries in this field, have tried to clarify things by formulating strict definitions and distinctions. The best known is Evans-Pritchard's proposition – on the basis of the distinctions the Zande, the subjects of his first book, supposedly made – to distinguish witchcraft and sorcery: the first referring to an inborn quality, the second to the use of acquired means. But even for neighboring areas in Africa this distinction proved difficult to maintain in view of the fluidity and dynamics of witchcraft discourses. More recently, some authors (see Geschiere, 1997, 2013) suggested that this search for clear-cut definitions and classifications risked to make anthropologists blind to the surprising dynamics of these representations and their chameleonic qualities – which are, moreover, crucial to understand how they can adapt themselves so easily to modern changes. In this treacherous field of study, researchers may have to resign themselves to working with fuzzy notions that exhibit a common core, but at the same time engender highly variable and constantly changing elaborations.

The differences between the historians' and the anthropologists' versions of witchcraft are illustrative of the widely varying implications these notions can acquire. In general, historians paid more attention to the dynamics of these

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12165-8

representations. After all, a central question to them was why persecutions of witches – quite rare throughout what was sometimes called the 'dark' Middle Ages – acquired epidemic forms in several parts of Western and Central Europe, precisely at the dawn of modern times (sixteenth and seventeenth centuries). Historians like Robert Mandrou or Norman Cohn explained this as the effect of a longer process of the diabolization of local witchcraft beliefs. Popular worries about perpetrators of evil within the local community (*maleficium*) increasingly became linked to ecclesiastically inspired visions of a Satanist cult. In the confessions of people accused of witchcraft – increasingly obtained under torture by the henchmen of ecclesiastical and secular courts – the Devil emerged as the leading figure at their nocturnal meetings. Some historians related the quite sudden proliferation of witch-hunts after 1500, therefore, to the disciplinary action of the State and the Church that ever more affected the local communities. Muchembled (1978), for instance, saw a clear distinction in the archives between two discourses: the one of the witnesses who accused their neighbors of destroying corps, cattle, and even human lives; and the one of the judges who forced the accused to relate all this to their dealings with Satan. Thus, Muchembled construed a direct link between the witch trials, on the one hand, and, on the other, the rise of the absolutist State and the religious struggles inspired by Reformation and Counter-Reformation; he saw the witch trials as an emanation of the 'forced acculturation' of popular culture by a 'triumphant centralization.' However, in the beginning of the 1970s other historians, mainly working on England, had already advanced another explanation, emphasizing rather the increased willingness of notably rural people to accuse their fellow villagers. Thomas (1971), for instance, related this to the deepening inequalities within rural communities. Richer villagers increasingly resisted older obligations to share with their poorer fellowmen, translating feelings of guilt about this into witchcraft accusations. In this view, State and Church were rather drawn into these affairs by pressures from below.

Thus, there seemed to be a more or less clear contrast between a continental pattern – that for some time also affected Scotland due to dynastic links with Denmark – in which State and Church authorities played a key role with their obsession with the Devil; and a quite different one, prevailing in England, in which locals pressurized the authorities to do something about the *maleficium* of the witches in their midst. More recently, however, this contrast was nuanced by several authors (see Briggs, 1996), who emphasized that on the continent as well, tensions and accusations within the local communities played a key role, while direct involvement of State or Church authorities in the persecution of witches was the exception – certainly in the most absolutist States (France, Spain) – rather than the rule. Moreover, they signaled that in England as well, Satan came to play an increasing role in the witches' confession, be it belatedly and less prominently. Yet, despite such different emphases, historians' interpretations have in common the premise that witchcraft cannot be analyzed as a purely local issue but has to be studied in relation to the intervention of outside agents, notably the State and the Church. After all, their main sources – court archives – were produced by the latter. An attempt by Ginzburg (1990) to relate the imaginary of the witches' Sabbath to a set of folk beliefs – going back to Neolithic times as some sort of substratum throughout Eurasia – received a lukewarm reception and clearly fell outside the historians' main paradigm.

Anthropologists, in contrast, for a long time continued to address witchcraft as a local issue, trying to resolve its riddles by in-depth studies of local relationships and conceptions. But the anthropological perspective as well was subject to constant turns, some of which were quite surprising. An obvious question is why especially Africa and Melanesia loomed so large in anthropological studies of witchcraft. However there was a change in this respect over the last decades due to publication of seminal studies on witchcraft in different parts of Asia, Latin America, and other parts of the world (cf for instance Whitehead and Wright, 2004; Siegel, 2006; Buyandelger, 2013). In retrospect it seems that other notions – like shamanism, voodoo, magic – were used to refer to ideas and practices that had much in common with what was referred to elsewhere as witchcraft. There was also substantial turns in the anthropological perception of these ideas and practices. Evans-Pritchard's Azande study, already mentioned above, is often quoted as a classic in the field. Yet it hardly proved to be a trendsetter. Its focus was on issues of cognition – on why the Azande combined very commonsensical explanations with interpretations in terms of occult aggression. But it inspired in the 1950s and 1960s, a series of micro-political studies in which witchcraft was analyzed – in line with the functionalist ideas that dominated the discipline at the time – in relation to social order and integration. In a series of in-depth monographs of local societies in what at the time was called British Central Africa, anthropologists of the 'Manchester school' studied witchcraft accusations as a form of social control. Typical for this approach was Max Marwick's characterization of witchcraft as 'a social strain gauge': as a measure of sociopolitical tensions, but also as a way to restore social order. It was this interpretation that produced the in retrospect somewhat amazing view of it as 'tame' and 'domesticated' (see quote from Douglas above). However, especially toward the end of the last century, this conception of witchcraft as a conservative force, defending the status quo, was increasingly felt to be too limited in its focus on the local context. Anthropologists also were forced to study these supposedly 'traditional' discourses in the context of broader changes.

Witchcraft and Modernity

It is questionable whether the functionalist view of witchcraft, as restoring social order, applied even during the colonial period. At the time researchers may have underestimated to what extent the imposition of the *Pax Britannica* (or *Gallica*) played a role in this respect. But it is clear that this view hardly prepared anthropologists to confront the quite spectacular dynamics of representations of the occult after Independence (in most African countries around 1960), especially in the more modern sectors of society. It is difficult to decide whether

accusations and rumors, let alone actions, in terms of witchcraft increased after Independence (just as the old debate among anthropologists on whether witchcraft 'increased' or 'decreased' after the colonial conquest had no conclusive ending). But it is quite clear that it came out into the open, in many parts of postcolonial Africa. Witchcraft became a hotly debated issue, not only in the street rumors of *Radio Trottoir*, but also in newspapers, on TV, etc. It was striking, moreover, that rumors and references to the occult forces proliferated especially in more modern contexts: in relation to novel forms of entrepreneurship, national politics, sport, and the new institutions for health care and education. The view, to many still self-evident, of witchcraft as a 'traditional' relict that will automatically disappear with modernization – 'witchcraft will disappear with electric light' as a Dutch missionary in Cameroon told me in 1971 – became difficult to maintain in consideration of the popular tendency to address precisely such modern developments in terms of these occult discourses. Neither did the anthropological image of witchcraft, as a local phenomenon, proves to be of much use for understanding the spectacular increase in scale of these rumors that acquired national or even transnational dimensions. No wonder that after the 1960s, anthropologists – also afraid of being accused of primitivizing Africa and denying its rapid modernization – tended to abandon the topic to theologians and journalists. The then-current anthropological approach in terms of social order proved to be of little help in analyzing the new transformations of these local beliefs.

In many parts of Africa, however, there was increasing popular concern about new forms of witchcraft that often were explicitly related to the *nouveaux riches* who were supposed to accumulate wealth by exploiting the labor of their witchcraft victims. Such rumors made a contrast between older forms of witchcraft in which the victims were 'eaten,' and the new one of 'selling people,' – that is, turning them into some sort of zombies to sell them to work on 'invisible plantations.' The fear of such new threats triggered a frantic search for new forms of protection – for instance, urgent appeals to the State authorities to intervene. An unsettling example of how pressing the witchcraft issue was becoming in situations of rapid change was the lethal witch-hunts that marked the end of Apartheid in the northeastern part of South Africa – young men, encouraged by *nganga* (witch-doctors) and claiming to act as local representatives of the African National Congress, executing dozens of 'witches' (Niehaus, 2001). The half-hearted implications of State authorities in such witch-hunts in many parts of the continent made it all the more urgent to gain deeper insight into the modern dynamics of witchcraft discourses. In this context, historical studies of the witch-hunts in early modern Europe served for some anthropologists as an eye opener, since the former had always emphasized the crucial role of external powers and wider political developments – the state and ecclesiastical courts impinging on peasant societies as representatives of the emergence of the absolutist state – in the explosion of witchcraft rumors and accusation at the local level.

No wonder that since the early 1990s there came a new wave of witchcraft studies in Africa and Melanesia, notably by anthropologists concentrating on the relation with popular views of 'modernity' – that is, the dreams of the modern, in all its varieties, that effected ever wider strata of the population (cf Comaroff and Comaroff, 1993; Geschiere, 1997; Ashforth, 2005). This linking of witchcraft and modernity, according to some even a new 'paradigm,' implied attention to particular aspects that could explain the continuing resilience of these local beliefs – notably their circular character, their moral ambiguity, and their striking capacity to relate local realities of the family and the home to global processes of change. The circularity of witchcraft discourses is expressed most vividly in the paradox that the main protection against witchcraft often is to be sought in the very same field. In many parts of Africa, for instance, the *nganga* (healer) is supposed to be able to offer protection and healing only because of his (or her) overdeveloped witchcraft. In some societies there is a consistent effort to conceptually or even institutionally separate the *nganga*'s (or the chief's) occult power from the evil forces of the witches. Then witchcraft seems to be, indeed, unequivocally evil. But in practice, such distinctions between positive and negative forms of occult power are often highly precarious and controversial. In many African societies, for instance, *nganga* remain highly ambivalent figures – healers but at the same time suspect because of their dealings with extremely dangerous forces. The *nganga* is, therefore, also a striking example of the moral ambiguity of these forces. Basically these forces are certainly evil, but – as in the *nganga*'s case – they can be canalized and used in a constructive way. In this more positive sense, witchcraft – it is in such a context that this English translation of African notions becomes, indeed, problematic – can even be seen as a precondition for accumulating wealth and power.

This applies most strikingly to the new modes of enrichment that seem to bring out ever more starkly the ambivalence of witchcraft conceptions: the rumors, mentioned above, about the new witchcraft of wealth that turns its victims into zombie-laborers express horror about such treacherous attacks, but also fascination with the new riches thus acquired. It is these ambiguities that give witchcraft discourses their elasticity and their surprising capacity to relate the global to the local. In most parts of Africa and Melanesia these discourses still are rooted strongly in the local setting, notably in the intimacy of kinship: witches are supposed to have a special hold over their kin or in any case to work through an ally 'within.' Yet, the same discourses are invoked to cope with the unsettling modern developments: the vagaries of the world market, the dazzling riches of the happy few, and the recurrent mishap of the many in their pursuit of the new forms of wealth. In such contexts, witchcraft rumors can attain truly global dimensions referring, for instance, to the circulation of zombies on a world scale or to the appropriation of extremely potent 'medicine' from Europe or India.

Such anxieties about hidden aspects of modern developments are certainly not special to Africa or Melanesia (cf the seminal studies by Taussig, 1987; Kapferer, 1997 on, respectively, Amazonia and Sri Lanka). The new anthropological interest in the paradoxical link between witchcraft and modernity inspired also alternative readings of developments in what are thought to be typically 'modern' societies. In this context there was increasing interest, among Africanists and others, in anthropologist Favret-Saada's challenging studies of

the resilience of witchcraft practices in the French countryside (1977). Truly innovative elements in her analysis were the emphasis on how words can become charged, and also on the inevitability of the researcher herself becoming involved in the struggles for protection against secret attacks. In a more direct relation to modern forms of politics and communication, Geschiere (in Meyer and Pels, 2003) drew attention to intriguing parallels between witch-doctors and 'spin-doctors' in respective African and American politics – both manipulating esoteric expertise and 'public secrets' that shroud the exercise of power. In her detailed analysis of rumors on Satanism and child abuse in present-day England, La Fontaine (1998) demonstrated the relevance of anthropological witchcraft studies on Africa and Melanesia in such a modern context. The broader interest of these new directions in the study of witchcraft, often still seen as the archetype of the traditional, was precisely that they helped to debunk simplistic opposition between modern and traditional, science and magic, transparent and opaque, or even more simply between the West and the rest. Clearly, even in the West modernity, witchcraft retained its own forms of enchantment and opacity.

Paradigms and Critiques

However, after 2000 a rapid reaction against this emphasis on modernity set in, especially in African studies. More than among historians, anthropological approaches to witchcraft seem to progress – or in any case continue – in a jerking movement since it has become common practice that scholars construe the work of their predecessors into a 'paradigm.' Apparently an attraction of the latter is that it automatically implies limitations, and therefore the challenge to break out of these. As noted before, Douglas contrasted the vision by her contemporaries of witchcraft as a system of social control to Evens-Prichard's epistemological approach. The anthropologists of the 1990 saw their emphasis on the 'modernity' of witchcraft as a breakthrough of the paradigm of classical studies with their emphasis on social control within a limited local context. But especially over the last few years younger anthropologists evoked a 'witchcraft and modernity paradigm' that would have determined the publications of the 1990s. The switch in the 1990s would have imposed a view in which witchcraft had to be studied as a product by modernity, so that the longer historical trajectories of these notions and practices were ignored (see, for instance, Henry and Tall, 2008; or Stroeken, 2010). It remains to be seen whether any of the scholars to whom this 'paradigm' was attributed had such limited ideas. Critics often quote in this context Jean and John Comaroff's notion of 'occult economies' as a by-product of 'millennial capitalism' (Comaroff, 2000). But it is quite clear that their insistence on the generality of such occult economies in different parts of the world (and not only in Africa – still a very welcome contribution to undermine tenacious ideas about this continent's otherness) does not preclude close attention to the specific forms such occult economies acquire as products of specific histories. Moreover, it is hard to believe that anyone would ever think witchcraft to be only about modernity (indeed, in present-day contexts in many parts of Africa it seems to become an almost empty signifier that can refer to anything). Amidst the clamor of such critiques, Todd Sanders' formulation is a very wise one: "African witchcraft may well be part *of* modernity, but by no means needs to be *about* modernity" (2003: p. 338). The merit of the switch in African witchcraft studies in the 1990s may have been that it raised the question how local discourses on occult forces could be so easily grafted upon incisive modern changes. But this link with people's visions of modernity should certainly not become a final truth. Most scholars – also the authors who supposedly initiated this paradigm of witchcraft and modernity – will agree that there are many more aspects to be taken into account.

In certain respects this turn in anthropological debates around 2000, resembled the turn that took place a decade earlier in the debates among historians about early modern Europe. As noted above, in the 1990s ever more historians turned against the emphasis by Robert Muchembled and others on the 'civilizing offensive' by State and Church against popular culture as an explanation for the unleashing of bloody persecutions in the sixteenth and seventeenth centuries. The trend in historical studies became also to see the role of Church and State in a broader context, taking a wide array of varying factors into account to understand outburst of persecutions. A particularly convincing example of such a broader approach is Thomas Robisheaux' beautiful and disquieting monograph on *The Last Witch of Langenburg* (2009). In this study of the last burning of a witch in Württemberg (Germany – 1672) the author succeeds, through a creative use of all sorts of sources, to evoke such a vivid and detailed image of the series of events that led to the execution of Anna Schmieg, the miller's wife, that many anthropologists will envy him for such a complete picture. Striking is especially how the role of the local state and the representatives of the Lutheran church turns out to be only one element – next to local customs, pressures from the community, and so on – of a collective moral effort of frightening intensity to make the woman confess of her dealings as a witch with the devil. The hold of the latter over the community could only be broken if the woman could be forced to confess. Apparently any means – torture but also constant moral admonition – was permitted for this.

Themes

Underneath these somewhat noisy transitions from one 'paradigm' to another, themes emerged that can be of great value for further developments in the field. One promising direction already mentioned above was the emphasis on the circularity of witchcraft discourse, and the ambiguity in the role of healers – implying that the protection against these occult forces had to be looked for in the field of these forces themselves. Related is the emphasis on the capacity of these representations to relate the global to the local – to explain new developments in terms that are rooted in the local realities of family and home. Pursuing these lines of thought, there was growing interest in the ambiguous relation between witchcraft and the intimacy of home. For a long time anthropologists, especially those working in Africa, had

already stressed the close link between witchcraft and kinship. As noted, witches are supposed to have a special hold over their close relatives, and the instigators of an occult attack are always first sought within 'the house.' However, with the increasing scope of witchcraft rumors – now addressing issues that are far beyond the seemingly closed world of the village, studied by anthropologists in the 1950s – people's tendency to continue linking witchcraft conspiracies to the local realities of home and village is striking. This is certainly not a simple, unambiguous continuity. On the contrary, in many parts of Africa, for instance, people are now anxious about new forms of witchcraft because these would surpass the old limits of kinship (apparently witches can nowadays attack anybody, kin or nonkin). However, on closer inspection, cases often continue to refer ultimately back to the family and kinship – albeit in new, dynamic versions of what can still be interpreted as kinship. Indeed, the hypertrophied tenor of present-day witchcraft fantasies in many African contexts seems to reflect a constant stretching of kinship, almost to a breaking point. Kinship terms continue to be used to bridge increasing social and geographical distances. Yet, it is clear that this stretching with new forms of mobility puts the concomitant kinship norms under heavy stress. Even transcontinental migrants feel now persecuted by the dangers of home. So, rather than take the link between witchcraft and kinship (or more largely, intimacy) for granted, the challenge might be to follow the ambiguities of this link in rapidly changing contexts – and also in its changing implications for the issue of trust and the question as to how one can ever succeed in building confidence in one's intimates if they have such a dangerous hold over you. This link between occult dangers and intimacy – and its problematic implications for trust – is not special to Africa; on the contrary, it returns in many parts of the world, all be it in different forms following different historical trajectories. In such a comparative view, people's obsession with witchcraft in Africa or Melanesia is no longer that exceptional (see further Geschiere, 2013).

Other topics looming large in the study of witchcraft are the relations with healing and, closely connected to this, with the new churches, notably those of evangelical signature. The central role of issues of witchcraft in the rapid spread of Pentecostal churches in many parts of the world – in contrast to many older churches, Pentecostals offer a direct cure for witchcraft – is only one example of witchcraft fears being central in the impressive flowering of prophets and spiritual healers in Africa and elsewhere. Mary (2009) shows in a most interesting comparison of the role of prophets in Gabon, Benin and Ivory Coast different trajectories in the way these *visionnaires* deal with witchcraft and development, in relation to different political contexts. In a challenging vision, Joseph Tonda (2005) tries to definitively break away from the conceptual opposition between the forces of modernity, on the one hand, and the logic of witchcraft, on the other, by evoking the figure of *Le Souverain moderne*. This amoral figure dominates postcolonial forms of governmentality in postcolonial Africa, emerging from an osmosis – a 'magma' – of all these elements. It is precisely by realizing the full complexity of *Le Souverain moderne* that scholars can finally break out of the premise of a 'great divide' opposing the forces of modernity (or 'the work of God') and *l'esprit sorcellaire*.

Terms and Their History

Another difference between historians and anthropologists is that the latter keep worrying about the terms to be used in academic analysis. With some historians such terminological hesitations led to a certain impatience. Behringer (2004: pp. 3 and 216) reproaches anthropologists, for instance, that their constant worrying about terms blocked comparative studies. It is clear that in this marshy field a definitive terminological purity can never be reached. All terms adopted by academics will be polluted by their colloquial use in addressing highly ambiguous and polyinterpretable phenomena. However, more recently, debates about terminology among anthropologists went beyond quibbles over definitions and distinctions by focusing on the historicity of the terms involved. One can agree that all these notions of Western origin (witchcraft, sorcery, *sorcellerie*, magic, and so on), offer partial translations of local notions that are often much broader in their implications. Yet, rather than try to put a ban on such notions – which is redundant in view of the great currency of these terms, a more interesting approach might be is to try and follow the detailed history of how these notions became attached to local terms, and what the implications of these translations were (see for an early example of this approach B.Meyer's monograph on 'translating the devil' in Ghana – 1999).

An inspiring example is provided by the recent book by Andrea Ceriana Mayneri (2014) who – due to a most creative use of missionary archives, combined with intensive fieldwork on the spot – reconstructs how in the 1930s the word *sorcellerie* was imposed on local notions among the Banda in the Central African Republic due to precarious misunderstandings between missionaries, civil servants, and interpreters. Clearly this misunderstanding proved to be a 'working' one, since from then on the word *sorcellerie* deeply marked the evolution of the Banda imaginary on these occult forces. In a similar, but more general vein, historian Florence Bernault (2009) explores the switch in the late colonial literature on French Equatorial Africa from *fétichisme* to *sorcellerie*. Important is, in her view, that the word *sorcellerie*, like witchcraft, retains certain premises colored by Western academy, in a time that ongoing secularization was seen as the normal evolution. In this line of thought *sorcellerie*/witchcraft would refer to the supposed impossibility to separate politics and religion in African societies, which thus were marked as some sort of counterpoint to modern, secularizing society. In Bernault's view, academics should be more conscious of the fact that the term still carries such connotations.

One can wonder whether the dynamics that terms – also academic ones – acquire through their daily use in society, is not of importance in this context. The general appropriation of these notions by Africans has set in motion certain shifts. Similarly, on the side of academics, more recent uses of the term may be marked by the general realization that modernity is not bringing a general tide of secularization. The 'return of religion' – even in the supposedly secularized societies of Europe – may shift also the implications terms like witchcraft had to the people who originally imported those notions to Africa and other parts of the world. Due to such shifts the resilience of what people call 'witchcraft' in, for instance, Africa may also affect people's views in

societies that consider themselves thoroughly modernized (is this the explanation of continuously rising interest in phenomena like witchcraft in America and Europe?). Yet, such comments do not preclude the great value of a more historical approach to the issues of terminology that keep plaguing the study of witchcraft. Following in detail the introduction of this and parallel notions and the effects of their appropriation by the population can help us to get at the heart of the issues raised by this mesmerizing and at the same time highly productive cluster of images, rumors, accusations, and practices.

The same authors emphasize also that more attention among academics to what they take on board by adopting certain terms – also when taking them over from general parlor in the societies concerned – can make them more sensitive to their own role in the construction of witchcraft as a topic. One can wonder, though, whether in such reflections anthropologists have not a tendency to overestimate their own impact. In the field, the words of 'innocent' anthropologists – that is, those who have not been initiated – have not much power when witchcraft is concerned. After all, what can they see if they have not even the 'second pair of eyes'? Initiated anthropologists on the other hand – and many see initiation also for the researcher as a precondition for acquiring any knowledge in this esoteric field – are often supposed to be in a particularly dangerous situation since as neophytes they will be an easy target for ill-meaning colleagues. The power of the scientific discourse (which, indeed, constantly marks local people's formulations on witchcraft as a different kind of 'science') does not come from the anthropologist, but rather from representatives of powerful institutions like the medical services, the school, maybe the theologian and or the developer. The anthropologist is – certainly while in the field – often caught in an uneasy position between the two discourses.

Yet, it is clear that further analysis of the power of the words that we – not only the informants but also the academics – use, is one of the more promising directions in the field. How terminological issues can be placed at the heart of the analysis through an ethnographic approach, rather than by raising issues of definitions, is shown from a different perspective and with great theoretical sophistication by James Siegel's monograph (2006) on the 'naming of the witch' in the terrible outbursts of violence against witches in post-Suharto Java (end of the 1990s). Criticizing anthropologists' tendency to shy away from the full horrors of such episodes by falling back on a reductive approach – explaining witchcraft as an expression of something else – Siegel proposes rather to follow in detail what people do when they start using the word witch ([*dukun*] *santet*) that can trigger such wild violence. For him, the word is a desperate attempt to name something un-namable. Making a daring link between Kant's notion of the sublime and Freud's of the uncanny, he analyzes the word 'witch' as failing to close off an experience of the uncanny/sublime. Thus the great uncertainties and the violence it can trigger. Again, the challenging way in which Siegel relates witchcraft to experiences of the uncanny – for him a category that is of any time and any place, and always manifests itself in unpredictable way – can serve to place the experiences captured (often only partially) by a notion like witchcraft, at a more general level, making it more than just a sign of some sort of 'otherness' of the society or the people concerned.

Underneath all the changes and reorientations in the academic debates about witchcraft, some constant concerns remain. A crucial challenge to both historians and anthropologists – although the latter seem to wrestle with this more explicitly, due to their direct confrontations with the realities at stake – is how to face the strong presence of these imaginaries in the societies concerned, without contributing to 'othering' them – as irrational, prescientific, and nontransparent, or whatever peculiarities can serve to make these societies the 'Other' of the supposedly modern West. Or, to put it more directly, ignoring the generality of popular preoccupations in many parts of, for instance, Africa – as for early modern Europe – is an impossibility. But how then can we address them without 'primitivizing' the continent or the earlier period? Promising directions for facing this challenge can be found in the recent tendency to confront terminology, not in order to arrive at purer definitions, but rather in a historical and ethnographic sense by following the particular trajectories of these problematic terms in everyday life. Another way to confront this challenge might be through a broader comparative perspective, showing that the issues addressed by a notion like witchcraft emerge in maybe different but still corresponding forms in societies all over the world.

Abstract

Ludwig Wittgenstein (1889–1951) was a leading figure in twentieth-century philosophy of language and philosophy of mind. In his Tractatus Logico-Philosophicus, he devised a theory of logical truth based on a naturalistic metaphysics and a referential and speaker-oriented theory of the meaning of declarative sentences. Since its fundamental postulates turned out to be inapplicable to ordinary language, Wittgenstein made a fresh start, in his Philosophical Investigations, by grounding linguistic meaning in a sign's role in social interaction. Relevant ways of using signs have to be socially established; therefore, meaning is essentially public rather than intentional. Applied to first person sensation language, this resulted in public accessibility and social determination of subjective psychological states, all the more so since Wittgenstein treated verbal expressive behavior as a special case of expressive behavior in general. While very influential in philosophy, his ideas took little substantial effect in other areas. Semantic theories of meaning were influenced by the Tractatus, whereas the later ideas are still waiting to be transformed into research programs.

Life

Ludwig Josef Johann Wittgenstein was born in Vienna on April 26, 1889 as the youngest of eight children of Karl and Leopoldine (née Kalmus) Wittgenstein. His father was a protestant, his mother a catholic, and the children were brought up in catholic faith. Wittgenstein was of partly 'Jewish' descent (three-quarters according to Nuremberg laws), and he accepted this classification to the point of self-attributing character traits that counted as Jewish in the Habsburg monarchy of the turn of the century. (Weininger's *Geschlecht und Charakter* impressed him deeply.) The family had become one of the wealthiest of the Habsburg Empire in the iron and steel business, and young Ludwig got his early schooling from private teachers until his father decided to send him to the *Realschule* (technical gymnasium) at Linz in 1903, no doubt hoping him to become an engineer, where he passed his '*Matura*' in 1906.

The Wittgenstein home in Vienna was very *fin de siècle*. On the positive side, the house was open to artists and composers, the family exercising generous Maecenatism; Ludwig read intensively in his youth, and there is documented influence from Goethe, Schopenhauer, Heinrich Hertz, Karl Kraus, Wolfgang Köhler, and others. On the negative side, the children were attended more by staff than by their parents, and the sons had definitely self-destructive tendencies. At least two of Ludwig's brothers, possibly a third one, committed suicide, a tendency which Ludwig had to combat himself for most of his life. Looking back at his childhood, he considered it to have been unhappy.

Having graduated from the Linz *Realschule*, Ludwig went to the Technische Hochschule Charlottenburg (now Technische Universität Berlin) where he studied mechanical engineering and was awarded his 'Diplom' in 1908. He went to Manchester in the same year to do research in aeronautics; however, he began to develop a growing interest in pure mathematics and read Bertrand Russell's *Principles of Mathematics* of 1903 and Gottlob Frege's *Grundgesetze der Arithmetik* of 1893. Fascinated by these books' enterprise of deriving mathematics from logic, he visited Frege in Jena in 1911 who encouraged him to study with Russell in Cambridge. He was a student in Cambridge from 1911 to 1914, but although attending some classes in philosophy (notably with George Edward Moore), his work had more or less the character of an extended dialogue with Russell on questions of logic and the foundations of mathematics.

During his Cambridge time, Wittgenstein experienced the first of a number of deep emotional friendships with young men. Although he was homosexual, the relation with David Pinsent probably remained platonic until it was ended by the latter's death in World War I. One love relationship, with Francis Skinner in Cambridge in the 1930s, is known to have been fulfilled sexually, but Wittgenstein broke it off, just as if unfit for happiness in human bonds, and in addition, deeply ashamed of his disposition.

He volunteered for the Austrian army in 1914 and served, with distinction, throughout the war; extant diaries testify to ongoing work that was to lead up to his only philosophical book published during lifetime, the *Logisch-Philosophische Abhandlung*, which was actually finished in summer 1918 and first appeared, very poorly edited, in Ostwald's *Annalen der Naturphilosophie* for 1921. The book became famous only after an English translation, under the title *Tractatus Logico-Philosophicus*, had been published in 1922 when Wittgenstein, after having trained as an elementary school teacher, was teaching children in villages in Niederösterreich – evidently in order to live a morally meritorious life. However, he had to resign in 1926 because of punishing a schoolboy too severely, and he would probably have given way to despair had not his sister, Margarete Stonborough, asked him to build her new Vienna house together with his friend, the architect Paul Engelmann. (The building now houses the Bulgarian embassy.)

Philosophical contact with Cambridge had never been cut off completely. Back in Vienna, Wittgenstein had some philosophical conversations with members of the 'Vienna Circle,' notably Moritz Schlick and Friedrich Waismann. Thus, although a lecture by L. E. J. Brouwer is said to have given the last push, it was not completely out of the blue that Wittgenstein returned to Cambridge in 1928. Having given away his inherited fortune to his brothers and sisters after the war, he had to apply for a fellowship (submitting the now famous

Tractatus as a doctoral dissertation). This was his way of earning his living until his death, except for holding a chair in Cambridge from 1939 to 1947 and living on savings now and then. He held regular classes in Trinity College, laconically entitled 'Philosophy' or 'Philosophy for Mathematicians.' A difficult person and not popular with most of his colleagues, his teaching success with a small number of students was enormous and accounted for his burgeoning philosophical ideas to be spread far ahead of the posthumous publication of his constantly rewritten notebooks and typescripts.

Except during wartime, Wittgenstein regularly went to Vienna in summer and for Christmas to see his family. Also, he several times went to Skjolden on the Sognefjord in Norway where he had had a little solitary house built before World War I. In 1939, with the assistance of John Maynard Keynes, he succeeded in applying for British citizenship which allowed him to travel in '*Großdeutschland*' even as an Austrian 'Jew' and to arrange for two of his sisters to be declared 'Aryan' in exchange for transferring large valuta parts of the family money to the German Reichsbank. During World War II, he served different jobs outside the university that he considered more important than doing philosophy.

Wittgenstein's second book, the *Philosophical Investigations*, was more or less finished in 1946 – finished in the sense of Wittgenstein himself considering it as printable. But a general mood of dissatisfaction with philosophical results seems to have got an increasing grip on him. Even though he continued writing and discussing philosophical questions, he was suspicious of finished answers. Asking the proper questions was, in his view, the important thing – an attitude which he had developed in the 1930s and which he expressed more and more sharply. In this mood, Wittgenstein did not press for publication. Living outside Cambridge for much of his remaining time, he alternately sought company and solitude until cancer of the prostate, diagnosed late in 1949, had worsened so much that traveling became impossible. He died in Cambridge on April 29, 1951.

Philosophical Work

Wittgenstein's early (*Tractatus*) philosophy can be regarded usefully as an attempt at answering two questions: Why are logical truths true? How can we recognize that they are? He did this by inventing a theory of meaning which, in turn, was based on an ontological theory of the most general features of reality. Starting from the observation that logical truths, as he had come to know them from the work of Gottlob Frege and Bertrand Russell, are always syntactically complex, Wittgenstein first stipulated that there is but one way of constructing complex sentences from components, viz., by combining the components in a complex which is a 'truth function' of the components (if every single component is either true or false, this is sufficient for the complex sentence to be definitely true or definitely false). The components may be complex themselves; but according to a second stipulation, the combinatory process originally starts from components that are elementary sentences, i.e., sentences which are not truth-functional complexes of anything else. If a complex sentence has been constructed from n elementary sentences, there are 2^n different combinations of each of them being either true or false; this is the postulate of mutual independence of the elementary sentences which is characteristic of 'Logical Atomism.' If the complex sentence comes out as true in every such combination, then it is logically true (e.g., 'If it is neither raining nor snowing, then it is not raining' is true, no matter whether or not it is raining and whether or not it is snowing). This is manifest for anybody who understands the complex sentence; thus logical truth 'shows itself,' and both questions above are answered if every elementary sentence is either true or false. Here a third stipulation comes in: Every elementary sentence is a 'picture' of an elementary 'state of affairs' which either exists, in which case the elementary sentence is true, or does not exist, in which case the corresponding elementary sentence is false. Existing elementary states of affairs make up the 'world' as it is. By a picture, Wittgenstein means an isomorphic correlation of the simple signs (which he called 'names') whose concatenations form the elementary sentences and of simple 'objects' which make up the elementary states of affairs. Given a set of elementary states of affairs and a set of elementary sentences, normally there will exist several possibilities to correlate simple signs and simple objects while preserving isomorphy; the actual correlation, according to a further stipulation, is chosen by the speaker who correlates sentences with states of affairs by thinking a state of affairs as a sentence's sense. Since 'names' occur in many different sentences, this thinking of the senses of whole sentences reduces the alternative correlations and thus determines certain objects as the meanings of given names which can form other sentences; so the understanding of new sentences can be explained.

So far, Wittgenstein's stipulations add up to a referential and speaker-oriented theory of the meaning of sentences that explains logical truth. However, he added restrictions two of the most provocative of which are the following: First, the states of affairs that make up the world and are necessary for language to be meaningful are all natural ones; there are no moral or aesthetic states of affairs. Evaluative pronouncements are, therefore, nonsensical. Second, the fact that a state of affairs is correlated with a sentence as the latter's sense, or the fact that a speaker correlates sentences with states of affairs (and in consequence, names with objects) by this or that 'projection rule' is not itself a state of affairs, which means that any description of this correlation is nonsensical too. Wittgenstein accepted this consequence by declaring all *Tractatus* sentences nonsensical, even if helpful, in the book's last propositions. On which Frank P. Ramsey is said to have commented 'What you cannot say you cannot say, and you cannot whistle it either' (an allusion to Wittgenstein's popular gift of whistling entire pieces of classical music). A third restriction often goes unnoticed, viz. that the *Tractatus* theory of meaning is restricted to declarative sentences, excluding questions, imperatives, optatives, and interjections. Wittgenstein hoped these might be incorporated into his framework by proper analysis, without, however, attempting to do so; the same holds for his failure to even look for real examples of elementary sentences.

In a period of hard work from 1929 until about 1936 which it has become customary to call 'intermediate,' Wittgenstein renounced Logical Atomism, i.e., the supposition that elementary sentences are mutually independent; all candidates (e.g., simple color statements) proved to exhibit meaning

relations with other ones of the same kin (what is green is not red). So the idea of systematic dependency being co-responsible for meaning emerged. This fell in line with the new idea of devising a nonrepresentational (nonsymbolic) conception of meaning: pieces in chess have a meaning (a role), without representing anything, simply in virtue of their place in the rules of the game. If linguistic elements played a role in a system of rules for their use in social interaction, this might well suffice for their meaningfulness. However, the appeal to rules implied a problem of its own. If rules are identified by means of their linguistic expressions, there must be meaningful expressions for there to be meaning (an obvious interpretation regress), and if rules have to be agreed upon there must be rules to confer validity on the agreement procedures (an obvious ruling regress known from constitutional and international law). Sticking to the idea of meaning to be found in systems of rules, Wittgenstein invented one of his most famous tools, the 'language-game,' which he elaborated in the posthumous masterpiece of his 'late philosophy,' the *Philosophical Investigations*. A language game may be understood as a set of regularities in behavior, involving several people, where the use of certain elements (to be identified as linguistic on further inspection) on the one hand depends on what has been done and what the other circumstances are, and on the other hand is relevant for further things to be done subsequently, either by the 'speaker,' 'audience,' or by third parties. These regularities in behavior have to be rich enough to differentiate, e.g., statements from commands; thus 'The window is open,' if playing the role of a command, will evoke responses different from when it is used as an answer to a question.

Commands do not qualify as such simply by being followed by someone else's doing something. They occur only where the speaker has the required kind of authority, and the addressee, rather than actually doing something, has to do it. (This is why utterances with given meanings are possible only in a social setting that provides for the characteristic rights and duties–languages are embedded in 'forms of life.') Both facts can, in the event, be analyzed as certain rules being followed by the people concerned, and it is here that Wittgenstein's solution to the double-regress problem about rules sets in. Rather than asking how to identify or how to establish rules, he asked how behavior looks like if it is rule-following behavior. If behavior is rule-following, the rule it follows can be extracted from it in the following way. There is a description of the behavior that makes use of the rule although the people who follow the rule do not make any use of the rule themselves. With Wittgenstein, a behavior *B* follows the rule *R* if *B* conforms to *R*, if it is learnable and if it goes without saying, i.e., is mutually expected among the people concerned. This is not new to present-day sociology, of course, but it served Wittgenstein to cut off both regresses sketched above. Nobody among the people who follow the rule need be able to identify it, and it need not be enacted, or agreed upon.

Anchoring linguistic meaning in practices that are complex in such a way that they can truly be described as rule-following has the consequence that there is no linguistic meaning outside a community. Whether or not an utterance is a command depends on others to expect a certain person now to do something. Unless they expect the person to do so, the speaker has not uttered a command. Meaning an utterance in a certain way is not something a speakers achieve by exhausting their very own mental resources and capacities (it is not due to their capacity of 'intending' in a traditional sense). Saying something meaningful, as well as meaning something, depend on others to be prepared to understand the speaker in a given way. This implies one of Wittgenstein's most famous theses, viz. that there cannot be a language private to one speaker, i.e., a language whose signs have their meanings no matter whether or not others understand them or react to them. However, Wittgenstein argued his critique independently, thus providing indirect evidence for his social account. The only rule available to a 'private meaner' would stipulate something like: '*S* means *x* if and only if I remember *S* to have meant *x* in the past'; since what is to be explained, viz. '*S* means *x*,' occurs in the explanation, the only available rule turns out to be void.

Whereas this famous 'private language argument' has attracted much philosophical debate, a side effect has proved to be more fruitful. Wittgenstein used the language of sensations as his example and so proved, by implication, that it is not possible to report on one's own sensations by way of privileged inner observation. (For in an unproblematic situation of observation, using the right words is a test of the observer's linguistic competence; if others cannot interfere, reports on one's own sensations would have private meanings in the sense defined above.) The idea that there is privileged knowledge of one's own sensations (and other 'conscious' psychological states like moods, emotions, impressions, and the like) originates in the fact that speakers have a special authority in expressing them, and Wittgenstein took two ingenious steps. First, he pointed out that the speaker's privilege is just one case among others of utterances (often prefaced by 'I know' as in 'I myself know best what is good for me') which are privileged according to our social rules rather than epistemically. Second, he interpreted them, rather than as reports, as being meaningful in the same way as nonverbal expressive behavior is, viz. in virtue of playing a recognizable role in a behavioral pattern. Thus, 'Ouch' or 'I am in pain' are meaningful insofar as they occupy the place of crying in the series injury/crying/winning attention (a series that exhibits nicely the structure, which is characteristic of commands, of authority/imperative/expected behavior, or the structure of precondition/utterance/expected reaction that characterizes meaningful utterances in general).

By parity of reasoning, the symmetry of verbal and nonverbal expressive behavior implies a last important result. Just as verbal utterances owe their meanings to others' reactions, so nonverbal behavior expresses what it does in virtue of others' socially established response. Now if one cannot make head or tail of the notion of an inexpressible psychological state (as Wittgenstein argued at length), a person's psychological state is what he or she could express at the moment, and then what that person is feeling, thinking, wishing, etc. is co-defined by how others would react should he or she exhibit expressive behavior. Wittgenstein is, thus, the first philosopher to have touched the topic of what has come to be called 'Social Anti-individualism.' In an unduly neglected paper, Fleming (1978) has likened Wittgenstein's view of the interpretation of expressive behavior to the interpretation of pictures. Pictures owe their content to a civilization's way of seeing them. Their content is manifest because it is defined by established

interpretation. Just so, established responses to other persons' behavior are operative in determining their psychological situation. This is what distances Wittgenstein from Logical Behaviorism. Rather than being inferred from behavior, psychological facts are directly observable; and rather than just being ascertained by observation, they are dependent on external interpretation.

Although Wittgenstein developed his 'middle' and later philosophy in opposition to and correction of his *Tractatus* ideas, there is considerable continuity both as regards content and methodology. In point of content, Wittgenstein is sure to be the first philosopher in history who developed his philosophical ideas from thoughts about how it is that the elements of language have meaning. In this respect, our linguistic competence plays a role, with Wittgenstein, not unlike that of our epistemic abilities in Kant's far-reaching deductions outside epistemology. As regards methodology, Wittgenstein insisted, both in the *Tractatus* and in later writings including the *Philosophical Investigations*, that good philosophy has a peculiar task, i.e., that of clarifying obscurities that have been and are constantly being produced, either when scientists misunderstand what they are doing or when scientific or everyday questions and experiences are misunderstood and linguistically distorted by bad philosophy. This continuity has often been stressed, but for at least two reasons it should not be overestimated. First, the task of clarifying was all that was left over for philosophy in the *Tractatus* since its theory of meaning reserved all meaningful statements for the natural sciences. Second, the assignment was a piece of explicit methodology which Wittgenstein did not obey in practice. In contrast, Wittgenstein's later conception of meaning admits to philosophy every useful language-game (e.g., that of describing language-games), the assignment of the task of clarifying being motivated by his experience of how much linguistic distortion his own early philosophy had suffered from; and clarification meant method rather than methodology–there is sure to exist no other corpus of philosophical writing so densely packed with repeated demonstrations of how translating philosophical questions and theses into everyday language provides clarity. As an original contribution to our picture of what philosophy can achieve, Wittgenstein developed this clarificatory way of handling philosophical thinking into intellectual therapy. The real aim is achieved when the philosopher, by way of rectifying his distorted use of language, has come to see that there has never been any philosophical problem except for the riddles he got entangled with by falling prey to the temptation of highbrow speaking. Wittgenstein went so far as to say that after such therapy, there was no place in philosophy for controversial theses or theories. Whereas many take these declarations at face value, others have argued that in view of the substantial and controversial achievements of his later philosophy, the declarations should be either interpreted in a restrictive way or taken as overstating an otherwise valuable methodological warning.

Impact

Wittgenstein's influence on the intellectual life of the twentieth century has not been uniform or coherent; early and late philosophy, written work and teaching contact, work and personality have appealed to different interests. The general public has been and still is mostly interested in his disconsolate life; following the arbitrary turns of fashion, he has been canonized in a way that would, to his utter disgust, have nowadays turned him into an unwilling victim of talk shows. Furthermore, Wittgenstein's prose style has been all the rage since the *Tractatus* was published, and whereas every Tom, Dick, and Harry arranged their texts in decimal notation before 1953, quoting aphorisms from the *Philosophical Investigations* became imperative for feuilletonists in Anglo-Saxonia from that date, and in the German speech area after 1960 when Suhrkamp had timidly published a joint edition of both of Wittgenstein's masterpieces (together with a '*Beiheft*' in order to secure respectability for an unknown Austrian–British philosopher by documenting the interest of poets like Ingeborg Bachmann).

As regards more serious questions, research has been affected differently by the *Tractatus* and by subsequent work, and by the latter differently depending on whether people were confronted with Wittgenstein's teaching in Cambridge or with his writing. The *Tractatus* gained a great popularity soon after the publication of the bilingual edition in 1922, and it exerted considerable influence on some of the members of the 'Vienna Circle' who had gathered around Moritz Schlick and were striving for a really scientific philosophy. The most enduring effect was to be the 'verification theory of meaning' which, as stated in the *Tractatus*, identified any proposition's meaning with the set of distributions of 'true' and 'false' to its elementary sentences which make the proposition true; elaborated by the circle's most influential member, Rudolf Carnap, it made its way into logic, philosophical semantics (the present-day truth-condition semantics), and is even influential in linguistic semantics. Karl Raimund Popper's disclaimers notwithstanding, the *Tractatus* theory that only those sentences have sense which risk to wreck on experience is a clear forerunner of his falsifiability theory of cognitive significance, influential in sociology and psychology since the 1940s.

In his philosophizing since 1929, Wittgenstein influenced some bright Cambridge students who learnt, from his live example, that being sober, honest, and clear was more important than, and at least as attractive as, producing high-faluting and sloppy nonsense. Following the advice to rephrase any philosophical sentence in everyday idiom, they began to form a veritable movement, Ordinary Language Philosophy, which had its high tide in the 1950s and early 1960s. The most famous and most important representative was Gilbert Ryle, Oxford based but on friendly terms with Wittgenstein, whose seminal *Concept of Mind* of 1949 inaugurated Logical Behaviorism, to be superseded by Functionalism; so it is a safe guess that without Wittgenstein, present-day research on the mind-body problem would look entirely different. Further effects resulted from the publication of the *Philosophical Investigations*, jointly in German and English, in 1953; the impact in philosophy was heavy, but surprisingly small in linguistics (the reason being, perhaps, that John L. Austin's speech act theory won the day). At present, the most interesting developments, in the behavioral sciences outside philosophy, seem to be going on in Cognitive Science and in Ethnomethodology. In Cognitve Science, Hubert Dreyfus and others have argued forcefully that intelligent achievements

cannot be accounted for by supposing that subjects are following explicit rules but have to follow them implicitly in Wittgenstein's sense. This has been condensed into the prediction that the architecture of the brain's working is to be regarded as connectionist rather than computational. In Ethnomethodology, Peter Winch and others have suggested that without a Wittgensteinian conception of forms of life, an adequate understanding of alien societies cannot be attained.

On the whole, however, Wittgenstein's influence, on the behavioral sciences, has remained marginal outside philosophy. In particular, social anti-individualism is still awaiting proper conversion into research strategies, just as is an adequate use of Wittgenstein's conception of language games in linguistic pragmatics.

Women and Criminal Justice

Loraine Gelsthorpe, Institute of Criminology, University of Cambridge, Cambridge, UK

Abstract

This article outlines some general themes concerning perceived judicial paternalism toward women offenders, punishment for offences against gender roles, and the increasing use of imprisonment for women, as well as highlighting some positive policy developments concerning women and criminal justice and what we know about 'what works' with women. The article includes brief concluding reflections on what has still to be addressed in terms of recognizing women offenders as victims and not just offenders. Women's experiences of criminal justice, wherever they are, may also reflect complex intersections of injustices that characterize their lives.

The aim of this article is to provide an overview of issues relating to women offenders and criminal justice. There are three main sections:

1. general themes, which relate to women, crime, and criminal justice;
2. concerns about the increasingly high rate of imprisonment of women in a number of countries; and
3. policy developments concerning women and criminal justice and what we know about 'what works' with women.

The article includes brief concluding reflections on what has still to be addressed.

Introduction

In all countries where statistics are collected in routine fashion, the majority of convicted offenders and those given court sentences are men. Broadly speaking, offending by women differs in a number of important ways from offending by men: it is less common, less frequent, and generally less serious. In western countries, especially, the USA, Australia, Canada, and New Zealand, women who offend largely commit property-related offences (bearing in mind different legal terms and definitions in an international context).

What Do We Know about Women Offenders and Their Criminogenic Needs?

Historically, the study of crime has been male-centered and the criminal justice system's treatment of women has been imbued with assumptions about men. When the female offender has not been ignored, she has been pathologized and treated as abnormal. It is only recently that we have begun to recognize more nuanced accounts of women's pathways into crime, with acknowledgment that women do not offend as much as men and that their offending behavior is primarily of a less-serious nature. There have been periodic moral panics about women's crime, particularly in relation to violent crime and 'girl gangs,' but it is hard to sustain the arguments in this direction in light of the research evidence and statistical analysis of patterns of crime (Chesney-Lind and Pasco, 2013; Sharpe, 2012). Poverty features highly in women offenders' lives (Carlen, 1988; Wacquant, 2009a). Moreover, there have been consistent messages from the research literature on women offenders and from experienced service providers and service users (Sheehan et al., 2007) that women offenders tend to have a history of unmet needs in relation to sexual and violent victimization, physical and mental health, housing and income, and training and employment. Substance misuse and child care responsibilities often compound these problems. Desistance studies relating to pathways out of crime serve to highlight the complexity of factors relating to women's pathways into crime, while pathways out of crime point to the need for broadly based provision that can be individually tailored. Service providers in prisons and in probation/community corrections as well as researchers support claim that there may well be indirect relationships between abuse and mental health, labor market participation, and substance abuse, all of which are associated with risk of reoffending. In other words, 'victimization' creates psychological sequelae, which can lead to offending behavior (Sheehan et al., 2011).

What Do We Know about Women and Criminal Justice?

In a number of countries very little is known about possible differences in the treatment of men and women, but equally, several authors have reviewed and/or researched the respective treatment of women and men by the courts, although few offer straightforward support for 'chivalry' or leniency toward women even though this is an oft quoted claim about the treatment of women in criminal justice systems (see Gelsthorpe, 2001). Many British and American researchers, for example, point to the complexities in sentencing. In the UK, researchers have observed that women conforming to conventional roles are treated more leniently than those who do not. Hedderman and Gelsthorpe (1997) have pointed two differences drawn between 'troubled' and 'troublesome' women, the former being more deserving of leniency than the latter, though with little to distinguish them in reality. In the USA, Daly (1994) found that it was children and the family, rather than just women themselves, who were the focus of 'chivalry' or 'judicial paternalism' as it has been termed, as the courts sought to support and conserve the fabric of society.

Women's low share of recorded criminality has significant consequences for those women who do offend. They are often

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28100-2

seen to be 'doubly deviant,' for example, for having transgressed not only social norms but gender norms too. As a result they may feel that they are doubly punished – especially when informal sanctions and stigmatizing processes are taken into account. There is double jeopardy in women offenders being seen as worse than men; they are both failing individuals and failed women. One striking example of the impact of stigma, mainly on a female group of the families of serious offenders is offered by Condry (2006) who observes that relatives of serious offenders in the UK are shamed and that this stigma has its roots in ideas about familial blame and contamination.

There is particular concern relating to risk/needs confusions in dealing with women offenders. Correctional authorities have become increasingly concerned with assessing the risks and needs of offenders in recent years. This move toward risk/needs assessment can be seen as a contemporary manifestation of two residual concerns: predicting future offending and determining 'what works.' However, as Canadian researchers Hannah-Moffat and Shaw (2003) have highlighted, with international reverberations, the research behind these assessment tools rarely considers the gendered, racialized, or otherwise stratified characteristics of risk and need. Moreover, women offenders are typically characterized as scoring high on 'needs' and low on 'risk' but that in practice, sentencers sometimes confuse the two with consequential up-tariffing of women in the sentencing system or in terms of 'risk' coming to dominate overall approaches to women offenders. One such example concerns the 1990 Task Force on Federally Sentenced Women in Canada, entitled *Creating Choices*. The Task Force recommended the closure of the only women's penitentiary and replacement with regional facilities, which would recognize the low risk, specific needs and experiences of women, but alongside new initiatives, there has been a growth in high security arrangements, and the use of assessment tools based on men (Hannah-Moffat and Shaw, 2003).

Women's Imprisonment

One significant concern in recent years relates to the number of women in prison across a range of legal jurisdictions (relative to the seriousness and frequency of their crimes). The World Female Imprisonment List is based on statistics gathered from 187 prison systems in independent countries and dependent territories. It shows the percentage of women and girls within each national prison population. The world list is compiled from a variety of sources – in most cases from the national prison administration of the country concerned or from the relevant ministry of justice or equivalent (see: http://www.prisonstudies.org/info/worldbrief/wpb_about.php).

At a general level, in 2006, it was reported that more than half a million women and girls were held in penal institutions throughout the world, either as pretrial detainees (remand prisoners) or having been convicted and sentenced (Walmsley, 2006). But more specifically, 31.3% of the prison population in Monaco are women, 19.1% in Hong Kong (China), 8.7% in the USA, 8.3% in the Russian Federation, 8% in Chile, 7.5% in Spain and Australia, 5.9% in New Zealand, 5.5% in Scotland (UK), and 5.3% in Norway. In Scotland women represent about 5.5% of the overall prison population, but this is 4.6% in England and Wales and only 3% in Northern Ireland (Ministry of Justice, 2012; Berman, 2009). Interestingly, in African countries women constitute a much smaller percentage of the total in prison, although women may be subject to other forms of control and coercion of course (ICPS, 2013).

Increases in Women's Imprisonment

Women's imprisonment has increased dramatically in most Western jurisdictions at least; certainly in England and Wales and in the USA and Australia over the past 15–20 years as shown by increases in the numbers of women given custodial sentences (Kruttschnitt and Gartner, 2003). (N.B. There are a number of ways in which rates of imprisonment can be analyzed. The number of receptions or admissions to custody provides an indication of how many individuals are incarcerated over a given period of time – usually 12 months.) In Australia, the number of female prisoners increased by 57% between 1999 and 2009 (Australian Bureau of Statistics, 2009). The increase in women's imprisonment has been particularly dramatic in the USA. Between 1986 and 1995, the number of women imprisoned for drug offences in the USA increased by 888% for example, with the increase being especially marked in states which had introduced severe penalties for drug offences and particularly among black women (Frost et al., 2006).

There are similar increases reported in New Zealand (Harpham, 2010), Spain (Alameda, 2005) and, according to a Council of Europe survey completed by the Quaker Council for Europe, in Finland, Greece, the Netherlands, Germany, and Poland too; in half of the 28 states surveyed there had been increases in the number of women in prison (Quaker Council for European Affairs, 2007).

Data suggest that between 1996 and 2009 the women's prison population in England and Wales increased from 2300 to 4300 women and from 4.1 to 5.1% of the total prison population (Berman, 2009). Similarly, the average female prison population in Scotland almost doubled between 1999/2000 and 2008/09, from 210 to 413 and there was also a huge increase in the number of women remanded into custody (McIvor and Burman, 2011). (There are some notable exceptions to the pattern. In Canada, for example, Gartner et al. (2009) suggest that the female prison population overall has remained relatively stable, although with a marked increase in federal (state/national) prisons rather than in provincial (local) prisons.) Moreover, there is need for care in interpreting increases because large percentage increases can mask relatively small changes in numbers. But an important caveat here is that the increases around the world have been sufficiently large to cause consternation among policymakers, politicians, and academics alike.

Why Have There Been Increases in Women's Imprisonment?

There is seemingly little evidence that more women are being imprisoned because of an increase in serious offending. Rather, it seems that a complex range of factors are responsible, including legislative and policy changes that have impacted on women, as well as there being increasingly punitive responses to women who offend and suggestion that prisons may have become 'modern day social services' for

women in the absence of appropriate provision in the community. In the United States, for example, Kruttschnitt and Gartner (2003) suggest that the growth in the state prison population is due to an increase in arrests (particularly for drugs offences), increase in the length of sentences, and an increased likelihood of being returned to prison when in breach of the conditions of parole. Indeed, the 'war on drugs' might well be interpreted as a 'war on women,' with minority women being disproportionately represented in those imprisoned for drug offences (Chesney-Lind and Pasco, 2013). Thus, the introduction of mandatory minimum sentences for drug offences has had a direct connection with the increase in the number of women in prison. One problem here is that seemingly 'gender-neutral' sentencing laws often fail to distinguish between drug traffickers and drug 'mules' (couriers) who are often persuaded to carry drugs across jurisdictions with the promise of money for food and shoes for children.

There has been a significant development in England and Wales in this regard, with the Sentencing Council implementing changes to sentencing practice so as to recognize the vulnerability of some 'drug mules' (who tend to be women). The change in approach to 'drug mules' forms part of new comprehensive rules on drugs offences from the Sentencing Council for England and Wales (2012).

Other commentators have pointed to increases in arrest rates. Schwartz and Steffensmeier (2007), for example, point to and then explain an increase in female arrest rates in the United States by referring to an increased tendency to arrest juvenile offenders. New technologies for detecting drug use (such as urinalysis) may also have given rise to an increase in parole violations in the United States for failing random drug tests, with women being more likely than men to be imprisoned for a technical parole violation of this sort than for further offending (Chesney-Lind and Pasko, 2013).

Notwithstanding difficulties in discerning whether or not there have been *real* changes in girls' and young women's violent behavior or simply changes in public and police responses, it has also been suggested that the increased rate of imprisonment in the United States can be accounted for by increases in violent behavior among women (Yin, 2008). A similar conclusion was reached in relation to increases in the use of custody for women in Australia (Gelb, 2003), although it should be noted that there is no corresponding change in self-reported studies (Zahn et al., 2008). In England and Wales, there have been concerns about increases in girls' and young women's violence, although it is suggested that there is more media hype than real increases (Sharpe, 2012).

In England and Wales, the reasons for increases in women's imprisonment seem similarly complex. Gelsthorpe and Morris (2002) investigated changes in the nature and seriousness of women's crime, changes in the type of woman sentenced to imprisonment (in terms of previous convictions and so on), a move toward equal sentences for men and women, as well as changes in sentencing patterns, and increases in the length of women's prison sentences. Their overall conclusion was that women were committing more offences in 2002 than in 1992 but that there had been only a slight change in the *nature* of women's offending, mainly with respect to drugs offences (although mostly involving possession of drugs rather drug selling – in other words, not the most serious drugs offences). The 'type of women' imprisoned remained much the same as in 1992: most women were criminally unsophisticated, serving their first custodial sentence for property-related offences. They also noted that a general increased punitiveness (reflecting successive governments' 'tough on crime' stances) and the increased use of short custodial sentences may have impacted on women in particular.

Concerns about the Treatment of Women in Prison

Prison conditions continue to be of concern, from high security levels to strip searching, from the paucity of programs and appropriate training and work opportunities for women to the poor provision for women with children (with relatively few mother and baby units or appropriately situated play areas for young visitors). In England and Wales, Scotland, and Northern Ireland, respective reports signify that nearly two-thirds of women sentenced to imprisonment are responsible for children less than 18 years of age (see The Prison Reform Trust, 2012). We might add to these concerns, those about visiting distances for the families of imprisoned women in England and Wales (women's prisons being unevenly scattered throughout the country). Other concerns revolve around women's unmet health needs and the high rate of self-harm in prisons – not only in the UK (Plugge et al., 2006) but in other countries too (see, for example, World Health Organization data: van den Bergh et al., 2011). In sum, the deleterious effects of imprisonment are indisputable; women's general vulnerability makes the experience worse – not only for themselves but for their children too.

The United Nations Rules for the Treatment of Women Prisoners and Noncustodial Measures for Women Offenders (the *Bangkok Rules*) were approved by the Third Committee of the General Assembly at its 65th session in New York on 15 October 2010 (UN General Assembly, 2010). The rules not only acknowledge that many of the existing prison facilities worldwide were designed for male prisoners, but recognize that women prisoners are one of the vulnerable groups who have specific needs and requirements. The rules also emphasize that when deciding on pretrial measures for a pregnant woman or where a woman is a child's sole or primary caretaker, noncustodial measures should be preferred wherever possible, with custodial sentences only being considered where the offense is serious or violent. Rule 6 highlights the need for "comprehensive health screening to determine primary health care needs," including (under Rule 6e) "Sexual abuse and other forms of violence that may have been suffered prior to admission." Moreover, Rules 10, 11, 12, and 13 draw attention to the need for gender-specific health care and mental health care. Specific mention is made (in Rule 13) that "Prison staff shall be made aware of times when women may feel particular distress, so as to be sensitive to their situation and ensure that the women are provided adequate support." Under Rule 25 (1) it is stated that "Women prisoners who report abuse shall be provided immediate protection, support and counselling, and their claims shall be investigated by competent and independent authorities, with full respect for the principle of confidentiality. Protection measures shall take into account specifically the risks of retaliation." And under Rule 26 we learn

that "Women prisoners' contact with their families, including their children, their children's guardians, and legal representatives shall be encouraged and facilitated by all reasonable means. Where possible, measures shall be taken to counterbalance disadvantages faced by women detained in institutions located far from their homes." Yet there is wide recognition that countries fall short of these rules (see, for example, Malloch and McIvor, 2013).

In her searching review of vulnerable women in the criminal justice system in England and Wales in 2007, requested by the government following the death of six women in rapid succession in a single prison in England, Baroness Corston lambasted prison conditions and noted that what was needed was "a distinct, radically different, visibly-led, strategic, proportionate, holistic, woman-centred, integrated approach" (Corston, 2007).

Research and Policy Developments

The history of work with offenders is not replete with success, but the research base (particularly the meta-analyses) developed since the early 1990s in the UK and other parts of Europe (drawing especially on work in Canada) now strongly supports the position that effective work with offenders is possible. But there has been relatively little attention to 'what works with women offenders' among policymakers in different countries, leading to the claim that women are "correctional afterthoughts" (Ross and Fabiano, 1986). While the focus of campaigns has commonly been in the high numbers of women in prison, the lack of gender sensitivity in prisons, and lack of attention to women's specific needs, in the Western world in particular, there have been recent attempts to focus more directly on what we know about women offenders and their needs, and based on this, to divert them from crime in general and prison in particular.

Gender Responsiveness

Notwithstanding various developments in programs designed to address offending behavior in the 1990s, there are controversies regarding their suitability for all offenders (women, black and ethnic minorities, young offenders, offenders with mental health problems, and very high risk and psychopathic offenders). Offender treatment programs are typically designed for white, male, adult offenders, with only minor adaptations for other groups of offenders.

Indeed, the criminogenic needs that have emerged from research on men have typically been applied to women offenders. The problem is encapsulated very well in the reference to women as "correctional afterthoughts" (Ross and Fabiano, 1986). However, as indicated above, it has been argued that the concepts of 'risk' and 'need' are themselves 'gendered,' and that differences between men and women should be taken into account in devising intervention programs. There are also claims that what works for men will work for women too. But this is not so, and even promoters of the popular cognitive skills programs now acknowledge that there may be an issue around the responsivity of female offenders to cognitive skills programs.

One recent study in England and Wales has tried to take things forward by exploring women's lower rate of completion on the community-based General Offending Behaviour Programme. The study indicates that despite some similarities, the predictors of program completion not only vary for men and women, but also operate differently between them. The findings support the 'gender-responsiveness' position that men and women should be approached differently, and suggest, moreover, that men are more likely to engage in instrumental compliance and women more likely to achieve normative compliance (relating to compliance achieved though self-interested calculation and compliance based on values and the legitimacy of interventions, respectively) (Martin et al., 2009).

Attempts to facilitate gender responsiveness in programs and interventions have been hampered because the state of research and program development for women generally lags behind that for men, but we are able to deduce what is likely to work with women from educational and other areas of research as well as from emerging research findings. From educational research we learn most women prefer to learn in collaborative, rather than competitive, settings. If we put this alongside evidence, which suggests that women-only environments facilitate growth and development, we can see that the evidence adds up to a need to work with women in nonauthoritarian cooperative settings, where women are empowered to engage in social and personal change. In addition, 'women-specific' factors such as health care, child care, and mental health together with factors relating to race and gender combined need to be addressed (see Gelsthorpe, 2010).

New Initiatives

On the basis of analysis of work in Canada, Blanchette and Brown (2009) take us further in advocating the integration of a number of gender-informed theories and methodologies in responses to women offenders. Specifically, they recommend gendered pathways, the use of relational theory, strengths-based approaches, and the use of positive psychology, all of which are critical frameworks for intervention with women. We might add to this, the need for such interventions to be sensitive to 'trauma.'

There have been some important new initiatives that reflect this kind of thinking. In Scotland, we can turn to Centre 218, which has its origins in reviews following a series of suicides in Scotland's only prison for women. The Centre is based on the idea that female offenders should be able to get 'time out' of their normal (and perhaps chaotic and stressful) environment without resorting to 'time in' custody. The Centre thus serves as a diversion from prosecution and as an alternative to custody, and more generally it offers particular support – for detoxification, support and outreach to health, social work, or housing services. The ethos is therapeutic in intention and there is much emphasis on providing a safe environment for the women (Beglan, 2013).

There have been some interesting developments in relation to women and criminal justice in England and Wales too, including major funding and effort to divert women from both crime and custody (Hedderman, 2011; Gelsthorpe, 2010). Holistic services based in women's community centers have been set up in order to support women offenders (see Women's Breakout: http://www.womensbreakout.org.uk/). Of course,

there are questions to ask: do the developments reflect a new sense of responsibility toward disadvantaged women or might they be interpreted as an extension in the network of control and regulation (Wacquant, 2009b). What is perhaps at issue now is how the centers can be sustained in a market economy of justice and how they can provide hard evidence of positive impact beyond consumer views (Gelsthorpe and Hedderman, 2012).

In the United States, the National Institute of Corrections in cooperation with the University of Cincinnati (University of Cincinnati, 2013) has created a series of new gender-specific risk/need assessments for adult, women offenders. The assessments include: (1) a full instrument, the Women's Risk/Needs Assessment, which assesses both gender-neutral and gender-responsive factors and affords separate forms for probation, prison, and prerelease and (2) the Women's Supplemental Risk/Needs Assessment which is designed to supplement existing risk/needs assessments. The Women's Supplemental Risk/Needs Assessment is also available in separate forms for probation, prison, and prerelease populations.

Elsewhere in the United States, there are developments relating to gender-responsive programming in prisons (Lawston, 2013), and in Victoria, Australia, developments regarding diversion from prison and better community provision in relation to drug and alcohol support, family reunification, debt management, and independent living skills for example (Sheehan, 2013).

It is obviously impossible to provide illustration of all the new developments across different jurisdictions, but there is emerging evidence that provision for women offenders in the community should be women-only to foster safety and a sense of community and to enable staff to develop expertize in work with women; integrate offenders with nonoffenders so as to normalize women offenders' experiences and facilitate a supportive environment for learning; foster women's empowerment so they gain sufficient self-esteem to directly engage in problem-solving themselves, and feel motivated to seek appropriate employment. Thus what is required is the utilization of what is known about effective learning styles with women; a holistic and practical stance to helping women to address social problems which may be linked to their offending; links with mainstream agencies, especially health, debt advice, and counseling; capacity and flexibility to allow women to return for continued support and development where required, and arrangements for women to have a supportive milieu or mentor to whom they can turn when they have completed any offender-related programs. In addition, it is important to provide women with practical help with transport and child care so that they can maintain their involvement in the center or programme (Gelsthorpe, 2010).

At the same time, and thinking particularly of developing countries here, 'improvements' may amount to no more than the institution of a single family visit each year for women in prison. There have been no wide sweeping reforms, merely 'pockets' of progress.

Concluding Reflections

Increasingly, political swings and fiscal controls exacerbate the challenges in addressing women offenders' needs in appropriate and proportionate fashion. Across different jurisdictions and among academics, policymakers, practitioners, and campaigners there has been growing recognition that prison is not an appropriate place for women in conflict with the law. The prison has often been a focus for concerns about human rights violations, but a human rights perspective alone has not brought the much needed reforms (see, for example, Moore and Jemphrey, 2013). Moreover, too little attention has been given to human rights dimensions of community sanctions (regarding potential intrusion into family life or the lack of services that are specifically tailored for women).

What is recognized is that women in conflict with the law are often victims of abuse, subject to domestic violence, and poor. Power relationships shape vulnerability and pathways into crime. Some judicial and public support has been garnered for decarceration and community-based alternatives in some countries, but there is much further to go. Moreover, steadily increasing recognition of women offenders' victimization in some western countries is one thing, recognition of women's victimization as they are caught up in human trafficking and yet prosecuted for being illegal migrants or without relevant papers is quite another (Hales and Gelsthorpe, 2012; Troshynski, 2012).

At the beginning of the twenty-first century, new crimes and concerns have emerged: terrorism, cybercrime, human trafficking, and other human rights violations for instance, all of which have produced new ways of women being involved in crime as offenders, or indeed, as victims – a topic not covered here, except in passing (see Gelsthorpe and Larrauri, 2013). Moreover, it is always a challenge to draw upon experiences in non-UK and nonwestern countries, largely because the topic of women and criminal justice has received limited academic attention, but it is important to conclude with recognition that women's experiences of criminal justice, wherever they are, may reflect complex intersections of injustices that characterize their lives.

Abstract

In this article, we review the history of women in health care from several thousand years BC through the present day. Although women practiced medicine as early as 4000 BC, European medical education did not begin until the ninth century. We analyze the trajectory of women's roles in medicine, throughout the middle ages until the present time, culminating in a focus on women in eighteenth- and nineteenth-century American and European Medicine. We conclude by focusing specifically on the roles of women in psychiatry and the challenges which continue to be experienced by women in leadership in Western medicine in the twenty-first century.

In this article we will consider women in medicine and psychiatry, including the history of women's roles and contributions. We will provide data on the status of contemporary women physicians and discuss the challenges they face.

The History of Women in Health Care

Throughout history, women have been healers and caretakers, playing multiple roles as pharmacists, nurses, midwives, abortionists, counselors, physicians, and 'wise women,' as well as witches. As early as 4000 BC, there were women who studied, taught, and practiced medicine. The first known woman physician, Merit Ptah, practiced in Egypt in 2500 BC. According to Chinese records, in 1000 BC, women engaged in typical physician-like activities.

The Roman, Soranas, believed that women were divinely appointed to care for women and children. His criteria for practitioners included literacy, anatomic understanding, a sense of patient responsibility, and ethical concerns, particularly regarding confidentiality. Roman women physicians, however, were rarely permitted to perform in the same capacities and positions as men.

Women founded and staffed early hospitals in 260–220 BC. The deaconesses of the early Christian church developed the first public health systems (Shryock, 1959). By the eighth century, Arab medicine began to flourish. Since Muslim men were forbidden from having contact with women who were not family members, women cared for women. In Islamic Spain, women received medical education and were surgeons before the twelfth century.

European medical education formally began in Salerno, Italy, in the ninth century. By the tenth and eleventh centuries, women were thought to have studied there (Corner, 1937). When medical degrees were first awarded in CE 1180, however, they were awarded only to men. Women received special diplomas until the fifteenth century. A woman physician, Trotula, was an important eleventh-century academic and teacher at the University of Salerno. She wrote texts on obstetrics and gynecology and headed a department of women's diseases. Her contributions were significant because, at that time, women provided all obstetrical care and many had no training. Many of her accomplishments, and those of other women, however, were attributed to their husbands and sons. An early twelfth-century abbess, Hildegard of Bingen, was a healer, philosopher, composer, and scientific scholar who provided scientific data on nervous system regulation and an understanding of normal and abnormal psychology.

Women were ambivalently received when they expanded their traditional midwifery roles, and they generally were prevented from obtaining medical training or degrees. In England, the need for physicians during the Black Death of 1349 opened the way for women to practice medicine. Constanza Calenda, in 1423, became the first woman to formally obtain a medical degree. She lectured in medicine at the University of Naples. In the fourteenth and fifteenth centuries women practiced medicine in several European countries, but their practices were usually limited to bleeding, administration of herbs and medicines, and reducing fractures, in addition to midwifery. In some countries, women did practice as physicians, surgeons, orthopedists, and ophthalmologists, and it was generally believed that women were better able to treat women's diseases. However, there were also women physicians who served kings, royal families, and even the military.

Despite this apparent success, by the end of the fifteenth century the movement to exclude women from practicing medicine gained momentum and most were specifically limited to functioning as midwives. This coincided with the misogyny of Johann Sprenger and Heinrich Kraemer, in the *Malleus Maleficarum* of 1486, which laid out much of the philosophy of the inquisition. Witch-hunting focused on the 'spiritual and mental' inferiority of women. Even when active witch hunts subsided, their effects remained and women were eliminated from many medical roles. By the seventeenth century, when examinations and licensing procedures were required for physicians, women were rarely allowed to sit for required examinations (Nadelson and Notman, 1995).

Women in Eighteenth- and Nineteenth-Century American and European Medicine

In colonial America, the healing role of women was critical to the survival of the colonies, since medical care of families was the

responsibility of women. There were no medical schools and relatively few trained physicians in the colonies. Training was obtained by going abroad or by apprenticing to a practitioner.

In 1765, Dr John Morgan founded the first 'regular' American medical school at the University of Pennsylvania. By excluding women, the tradition of barring women from formal medical training in the United States began. Still, many women set up 'irregular' practices without diplomas, having apprenticed in homeopathic or eclectic traditions. Toward the latter part of the nineteenth century, US women began to study in the few US and European schools that admitted them, including some in Switzerland, Italy, Germany, Austria, England, Ireland, and Scotland.

In 1847, Elizabeth Blackwell became the first woman accepted to a 'regular' US medical school. When she received her MD degree from the Geneva Medical School, the New York State Medical Association censured the school. In 1850, Harriet K. Hunt, an 'irregular' practitioner in Boston, applied for admission to Harvard Medical School. She was admitted, but denied her seat when the all-male class threatened to leave if women (and minorities) were admitted. It was not until 1946 that Harvard Medical School finally admitted women.

By the mid-nineteenth century, three all-female medical colleges were founded in the United States: the Women's Medical College of Pennsylvania, one in Boston (now Boston University), and another in Cincinnati. Several US universities, including Syracuse, Michigan, Iowa, and California also accepted women (Luchetti, 1998).

During the Civil War, Dr Mary Edwards Walker was awarded the Medal of Honor, the most prestigious military award, for her performance as a military surgeon. She was, however, subjected to enormous criticism and the medal was rescinded in 1917 after a change in guidelines limited it to men in combat. It was reinstated in 1977 (Luchetti, 1998). In 1878 the National Eclectic Medical Association became the first medical society in the United States to accept women for membership, but full membership in the American Medical Association continued to be closed to women until 1915.

Negative attitudes about women physicians were supported by a 'new science' rationalizing the inferior status of women on biological grounds. This escalated early in the nineteenth century and persisted into the twentieth century. A book published in 1873 by a prominent Harvard professor, Dr Edward Clarke, concluded that higher education for women produced 'monstrous brains and puny bodies' as well as a host of other abnormalities in them and their offspring. His views were successfully refuted by the eminent feminist, physician, and scientist, Dr Mary Putnam Jacobi. The road continued to be difficult even for those women who managed to obtain training. Ann Preston, founder of the Women's Medical College of Pennsylvania, described the entry of women onto the wards of the Pennsylvania Hospital, "We entered in a body, amidst jeerings, groaning, whistlings, and stamping of feet by the men students … On leaving the hospital, we were actually stoned by those so-called gentlemen" (Alsop, 1950).

Denied hospital appointments, US women began to open their own hospitals and clinics. In 1857, Elizabeth Blackwell, her sister Emily, and Marie Zakrzewska established the New York Infirmary for Women and Children. In 1862, Zakrzewska founded a similar hospital in Boston. They also founded the Women's Medical College of the New York Infirmary in 1868. Believing that women received an inferior education, they sought to correct the problem by establishing rigorous entrance exams and longer clinical training than other medical schools.

By the end of the nineteenth century, there were many important successes for women. Dr Mary Putman Jacobi was the first woman elected to membership in the New York Academy of Medicine in 1880. In 1875, Emmeline Cleveland, Dean of the Pennsylvania Women's Medical College, became the first nonmilitary woman physician in the United States to perform major surgery.

The role of women in medicine, however, continued to be hotly debated. In 1881, Rachel Bodley, Dean of the Women's Medical College of Pennsylvania, surveyed the 244 living women graduates of the school and found that, despite persistent belief that training for women was wasteful, the overwhelming majority were in active practice. Those who had married reported that their profession had no adverse effect on their marriages, nor had marriage interfered with their work. Many early women physicians came from medical families and they joined family members in practice. By 1876, 0.8% of US physicians were women. By 1890, 35 US medical schools admitted women, and in 1900, 6% of physicians were women (Luchetti, 1998).

In Europe, 1866 saw Elizabeth Garrett Anderson open a dispensary for women and children in London during a cholera epidemic. People were grateful for medical attention, even from women. In 1874 Sophia Jex-Blake, Elizabeth Garrett Anderson, and others opened the London School of Medicine for Women. The medical hierarchy threatened to blackball any male who taught there, and no teaching hospital would allow women to practice. For several years women could not get the needed training for registration in medicine. In 1877, the Royal Free Hospital in London allowed women access to its facilities. The Royal College finally opened its exams to women in 1910.

In Canada the situation was no different. Dr James Barry (1797–1865), Inspector General of the British Army Medical Department and subsequently Inspector General of Hospitals for Canada, was discovered to be a woman after her death. She was the first woman doctor to practice medicine in Canada (Hacker, 1974).

Women in Twentieth-Century Medicine

Despite the prominence and contributions of many women, negative attitudes about women in medicine persisted. In 1905, the President of the Oregon State Medical Society stated:

> hard study killed sexual desire in women, took away their beauty, brought on hysteria, neurasthenia, dyspepsia, astigmatism and dysmenorrhea … Educated women could not bear children with ease because study arrested the development of the pelvis at the same time it increased the size of the child's brain and therefore its head. This causes extensive suffering in childbirth.
>
> Bullough and Voght, 1973

In 1900, women comprised 10% of the students at 18 medical schools, 50% at Boston University, and 40% at Tufts University. Johns Hopkins opened its medical school in 1893

with the financial help of women, who exacted the condition that women be admitted on the same terms as men, based on qualifications. By 1917, Dr Florence Sabin became the first woman full professor at that institution (Luchetti, 1998).

Abraham Flexner, in his Carnegie Commission Report on the status of US medical education (1910), stated: "Medical education is now, in the United States and Canada, open to women upon practically the same terms as men. If all institutions do not receive women, so many do, that no woman desiring an education in medicine is under any disability in finding a school to which she may gain admittance." Further, he stated, "Now that women are freely admitted to the medical profession, it is clear that they show a decreasing inclination to enter it."

Flexner's Report established medicine as an academic discipline in the United States, with high standards for training and practice. This resulted in the closing of many medical schools, often those that admitted women. Thus, the number of female physicians in the United States leveled off at between 4% and 7% until the 1970s. This was a lower percentage than in most other Western countries.

Other countries continued to report higher percentages of female physicians. In 1965, for example, 7% of US physicians were women, while in the Soviet Union 65%, in Poland 30%, in the Philippines 25%, in the German Federal Republic 20%, in Italy 19%, and in the United Kingdom and Denmark 16% of physicians were women (Lopate, 1968).

Medicine had generally been viewed as a male profession in the United States more than in most other countries. Some hypothesize that this occurred because medicine had higher prestige and income than many other professions. It is also likely that science requirements of US universities were not considered appropriate for women. Since the practice of medicine represented a melding of roles and responsibilities, the caretaking functions of physicians fit the 'traditional' views of women's roles, but the technological and instrumental aspects did not. Clearly different cultures have conceptualized these issues differently.

The choices of specialty have remained relatively constant since women were admitted to medical schools in the United States. Women have characteristically entered pediatrics, internal medicine, psychiatry, family practice, and, more recently, obstetrics and gynecology, anesthesiology, dermatology, radiology, pathology, and other medical subspecialties. The surgical fields have remained sparsely populated by women and, although the numbers have changed over the last few decades, the percentages have moved very slowly.

Regardless of specialty, academic and administrative appointments as well as other leadership positions have been almost exclusively held by men. In the 1970s, the fact that women tended to primarily assume clinical roles was used as an argument for increasing their numbers in medical school. It was believed that they could be counted on to meet the direct health care needs of expanding populations, and men could assume specialty roles.

The large numbers of women in medicine in many countries have tended to be relegated to low prestige and clinical positions. Women, as in the United States, were rarely elected to membership in national academies of medicine or science. In the former USSR, women were in positions that reduced the differentiation between doctors and paramedical workers. They were the *feldschers* (semiprofessional health worker or physician's assistant) and this was considered to be a female role. In China, the 1950s brought the 'barefoot doctors' who were local health workers and many were former midwives (Nadelson and Notman, 1995).

The large increase in numbers of women physicians in the early 1970s in the United States coincided with the civil rights, antiwar, and women's movements. At the beginning of the twenty-first century almost 50% of graduating medical students and over 20% of all physicians were women. By 2011–12, women represented 47.8% of medical school graduates and almost 30% of physicians (AAMC, 2012).

There continues to be significant disparity in the leadership roles of women in medicine. Although 37% of full-time medical school faculty are women, up from 29% in 2001, women remain underrepresented in the professorial ranks. Despite the fact that the percentage of women at each rank has increased about 7% on average over the past 10 years, women continue to be overrepresented in the lower ranks, e.g., 54% of instructors are women while only 20% of full professors are women. In 2012, only 14 of the 119 permanent medical school deans (12%) were women, up from 2004 when 10% were women (AAMC, 2012).

Although women make up increasing proportions of residents in each specialty, the distribution of women among various specialties has shown little fluctuation. The highest percentages of women in 2010–11 were in obstetrics and gynecology (82% of residents) and the lowest are in the surgical subspecialties (15.4% in neurosurgery and 13.6% in orthopedics). The percentage of women residents in psychiatry in 2011 is slightly above the average at 55.5% up from 50.7% in 2001 (AAMC, 2012).

Women in Psychiatry

Mental illnesses have always been viewed differently than other medical illnesses, because they were generally not seen as medical. Early historical references to the care of the mentally ill, dating from classical times, framed mental illness in terms of religion. Many civilizations had sanctuaries where religious rites were used to treat people. As pagan faiths lost favor, there was deterioration in the quality of treatment afforded to the mentally ill. Mental illness was increasingly viewed as caused by supernatural powers, evil spirits, or demons. It took many centuries before institutional care was comparable to what had existed in ancient times (Zilboorg, 1941).

The first 'morotrophium' or house for 'lunatics' was recorded in the Byzantine world in the fourth century CE. Pilgrimages were made by those suffering to shrines believed to eject evil spirits. One of the early morotrophiums (house for lunatics) was named for St. Dymphna. It was a home for mental healing run by women in CE 1200.

Over the next several centuries, asylums were established in many parts of Europe and the Middle East, often with the support and leadership of women. In the sixteenth century, the Sisters of Charity took in the mentally ill when hospitals refused to admit them (Tomes, 1994). By the seventeenth century, some French institutions began to train nurses to care

for these patients. In general, however, care was punitive and often inhumane. A seventeenth-century Swiss woman physician, Barbara von Roll, pioneered in the treatment of mental illness and opened the field of 'psychosomatic medicine' by documenting the connection between physical and mental health (Brooke, 1997).

By the eighteenth century mental illness was receiving greater attention in Europe and the United States. Although the focus was primarily on nosology and categorization, some therapeutic approaches included bloodletting, purgatives, dousing in ice water, and placement of the patient in a spinning chair until the patient lost consciousness. Benjamin Rush, the founder of US psychiatry, was an advocate of the latter method since he believed that congested blood in the brain caused mental illness, and the movement of the spinning chair would relieve it (Alexander and Selesnick, 1966).

During the nineteenth century, wives of US physicians entertained asylum patients in their homes, to 'calm a fevered mind' (Tomes, 1994). These women were often responsible for the 'moral' atmosphere of the institutions and advocated for respect and attention in order to promote recovery. Dorothea Dix was a pioneer in her efforts to care for the mentally ill and reform inhumane practices.

In the late nineteenth century, about 200 women physicians staffed US asylums (Lunbeck, 1994). In 1880, Alice Bennett became the first woman chief of a women's division at Norristown State Hospital in New Jersey. Bennett's unpopular and outspoken opposition to mechanical restraint and neglect of the chronically insane eventually caused her to lose her position (Barton, 1987).

By the twentieth century, increasing numbers of women worked with the mentally ill. The development of psychoanalysis in Europe attracted many women who were important in the development of the field. In 1923, the American Psychoanalytic Association admitted two women, Lucille Dooley and Marion Kenworthy to the organization. During this time Karen Horney began to challenge psychoanalytic theory, and a school of psychoanalysis evolved around her work (Menninger and Nemiah, 2000).

Over the course of the next few decades, many notable women psychoanalysts emigrated from Europe to the United States. Prior to World War II, 30% of European and 20% of US psychoanalysts were women (Chodorow, 1986). They contributed substantially to the growth and influence of psychoanalysis in the United States. Among the early women leaders were Clara Thompson, Hilda Bruch, Helene Deutsch, Phyllis Greenacre, Judith Kestenberg, Marianne Kris, Margaret Mahler, Edith Jacobson, Stella Chess, Frieda Fromm-Reichmann, and many others who pioneered as researchers and clinicians. Grete Bibring, a noted psychoanalyst, became the first woman to head a department of psychiatry in the United States (Beth Israel Hospital in Boston) and to become a full professor at Harvard Medical School.

Psychosomatics evolved in the 1930s with significant contributions of women, such as Therese Benedek and Helen Flanders Dunbar. Jimmie Holland was instrumental in founding the field of psychiatric oncology. Marion Kenworthy was notable in exerting an influence on the military, successfully facilitating an increase in the number of mental health units on army bases (Deutsch, 1959). In addition, Dr Kenworthy was a founding member and president of the Group for the Advancement of Psychiatry and became the first woman president of the American Psychoanalytic Association in 1958. She was elected as the first woman vice president of the American Psychiatric Association (APA) in 1965. Viola Bernard was a leader and founder of many psychiatric organizations and made pioneering contributions to child and social psychiatry (Menninger and Nemiah, 2000).

After World War II, women leaders emerged in organizations and academia, including, Eveoleen Rexford, Helen Beiser, Jeanne Spurlock, Mildred Mitchell-Bateman, and June Jackson-Christmas. It is notable that the latter three were African-American. Much of the leadership in the development of child psychiatry in the United States came from women, including many of those mentioned above. Melanie Klein developed internationally accepted theory concerning early life psychodynamic processes and Anna Freud contributed significantly to the understanding of ego development. In 1967 Evelyn Ivey became the first woman president of the American College of Psychiatrists.

As in other fields the numbers of women increased to almost 20% of psychiatrists in the 1970s but they continued to hold few leadership positions. Concern about women in leadership positions escalated enough to stimulate the APA to establish a Task Force on women, headed by Nancy Roeske. This led to the establishment of the APA Committee on Women. In 1973 Rebecca Solomon became the first woman appointed to the Editorial Board of the American Journal of Psychiatry. In 1974 the APA appointed Jeanne Spurlock to be the first Deputy Medical Director of Office of Child Psychiatry, Minority Affairs, and Women in Psychiatry. This was followed in 1976 by the appointment of Carolyn Robinowitz as Deputy Medical Director of the Office of Education.

In the 1980s and 1990s, women's leadership roles increased. In 1981, Judith Gold was elected as the first woman president of the Canadian Psychiatric Association and in 1984 Carol Nadelson was elected the first woman APA president (Sabshin, 2008). Since then, of the subsequent 24 APA Presidents, 7 have been women.

In 1984 Judith Rappaport became the head of Child Psychiatry at the National Institutes of Mental Health of the United States. Neuroscientist Nancy Andreasen became the first woman Editor in Chief of the American Journal of Psychiatry in 1992.

Other women leaders in psychiatry emerged during this time period in other parts of the world. In Australia, Beverly Raphael, the first woman to chair a psychiatry department in the country, became the first woman president of the Royal Australia New Zealand College of Psychiatry. Sarah Romans became the first woman Psychiatry Chair in New Zealand. Felice Lieh Mak, Chair of Psychiatry in Hong Kong, was the first woman elected President of the World Psychiatric Association, and Astrid Heiberg became a Professor of Psychiatry and the Undersecretary of Health in Norway, as well as President of the Norwegian Red Cross and later the International Red Cross.

Women psychiatrists who pioneered in research included Barbara Fish, who in 1955 began a long-term follow-up study of schizophrenic children. She was followed by Lissy Jarvik who was in the forefront of work on Alzheimer's disease, Nancy

Andreasen who pioneered the use of neuroimaging in psychiatric illness, Gabrielle Carlson and Paula Clayton whose work on affective disorders paved the way for future understanding of these illnesses, and Judy Rapoport who initiated research on early onset schizophrenia, hyperactivity, and endocrine function (Menninger and Nemiah, 2000). Nora Volkow MD, a leading researcher in substance abuse, was appointed Director of the National Institute on Drug Abuse in 2003.

Female Leadership in Medicine and Psychiatry: the Twenty-First Century

Although 55% of the trainees in psychiatry in the United States in 2013 are women, they remain in junior faculty positions in academic psychiatry as they do in the rest of academic medicine. They constitute 13% of US psychiatry chairs (AAMC, 2012). Women often lack research training and the kind of mentorship that will enable them to advance their careers. They are, less often than their male colleagues, offered research opportunities during training or at entry level academic positions, and they tend to work in clinical, teaching, and administrative positions that are time-consuming and do not facilitate the development of the necessary skills to enable them to progress academically. The pressures are greater for women interested in academic careers since they are in their peak childbearing years when they must also commit themselves to their career development (Nadelson and Notman, 1995).

Women in academic psychiatry, as in other fields of medicine in the United States, continue to be less likely to have peer-reviewed grants or publications than men, independent of parental status. A study of career development award recipients (K08 and K23 awards) emphasized that the career trajectories of men and women in academia differ. Both men and women award recipients tended to remain in academic medicine but women were less likely to receive R01, independent investigator grants and they published fewer papers (Jagsi et al., 2011). A 2011 paper supporting the differences in career trajectories indicated that women's publication numbers increase and exceed men's as they advance in their careers, but they continue to hold fewer leadership positions (Reed et al., 2011). These authors indicate that the disparity data suggest that mid-career assessments of academic productivity should not be a measure of future potential. Regarding academic rank these authors also found, as have other reports, that throughout their careers women were slower at achieving associate and full professor rank than men and they were less likely to attain divisional, departmental, institutional, or national leadership positions during the course of their careers. The usual reasons given for the lack of female leadership are that the numbers of women available are not sufficient, and/or that women are not motivated because of family responsibilities. The evidence has suggested, however, that men and women in similar cohorts have different career trajectories, and that women have not been promoted at the same rate as men, despite comparable qualifications (Tesch et al., 1995). Moreover, a 2011 analysis of the gender of editorial board members of 60 top-ranked medical journals of 12 Thomson Reuters Web of Knowledge Journal Citation Reports categories revealed that only 15.9% of editors in chief and less than one-fifth of all editorial board members were women (Amrein et al., 2011). Clearly, the numbers of qualified women have increased substantially but they are not being appointed. From a study of 4500 women physicians reviewing experiences of gender-based harassment, especially in historically male specialties, More et al. note that these early themes still resonate (More et al., 2009).

Another issue that has generated considerable discussion has been salary differential between men and women in academia as well as other fields. A study of gender differences in mid-career physician researcher salaries found that these differences do exist, when controlling for specialty, institutional characteristics, academic productivity, academic rank, and work hours (Jagsi et al., 2012). While there are many possible explanations for this disparity, gender discrimination or inequality remains an important consideration.

Another area of interest regarding the careers of men and women in academic medicine has been attrition. Levine et al. reported in 2011 that women leave academic medicine at higher rates than men. They suggest several determinants of this effect, including: lack of role models for family balance and career development, frustration regarding research funding and mentorship, work life balance, and institutional environments which discourage collaborative work and collegiality.

Despite contrary data, women's commitment, qualifications, and capabilities continue to be questioned and doubted more than men's. Discrimination, subtle harassment, and demeaning of women continue to exist. A study investigating gender bias demonstrated that when male and female names were placed on identical applications for the same positions, the male-named applicants were viewed as more competent, hired, and offered higher starting salaries than the female named applicants (Moss-Racusin et al., 2012). This type of study has been repeated over and over for many years with the same results, implying subtle and perhaps unconscious bias (Isaac et al., 2009). These authors also postulate that bias was eliminated when there was a commitment to the value of credentials before the review of applicants and when 25% or more of the applicants were women.

A summary of the issues faced by women as potential leaders begins with the difference in resources and opportunities offered to them as they begin their careers. Many studies repeat that women have greater problems with work/life balance, lack of family friendly policies and career flexibility, gender bias, and reduced support from senior leaders and mentors (Westring et al., 2012). Although we often assume that these issues are primarily experienced in the United States, studies from other countries echo the data and conclusions we have described (Goldacre et al., 2012; Riska, 2011; Van den Brink, 2011).

Psychiatry has a rich history of female contributions and leadership. If the field is to continue to evolve and expand its knowledge base, the culture must change. Women must play a vital role in the evolution of the field and innovations in research. Given that more than 50% of US trainees are women, their talents and potential contributions are essential to future progress.

Abstract

This article focuses on strategies and approaches to the study of women in Buddhism, women in early Buddhism (particularly as represented in the Pāli canon), women in Mahāyāna Buddhism, and recent developments in the Buddhist women's ordination movement, particularly as manifested in the Theravāda cultures of Southeast Asia. Attention is given to Buddhist attitudes toward and representations of women, the status of women as expressed through Buddhist textual discourses, and the concerns and perspectives of contemporary Buddhist renunciant women amidst the ordination controversy.

The subject 'Women in Buddhism' spans a period of over 2500 years and encompasses different Buddhist locales and traditions. From texts highlighting the Buddha's attitude toward women in fifth century BCE in India to current debates over women's higher ordination in Buddhist schools, women have been the subject of attention and concern throughout the history of Buddhism. They have also been actors and participants in the development of Buddhism. This article will focus on strategies and approaches to the study of women in Buddhism, women in early Buddhism (particularly as represented in the Pāli canon), women in Mahāyāna Buddhism, and, lastly, recent developments in the Buddhist women's ordination movement, particularly as manifest in Theravāda cultures of Southeast Asia.

Women in Buddhism: Strategies and Approaches

Historically, Buddhism has been a male-dominated enterprise in terms of the chiefly male authorship and perspectives of its classic texts and the predominantly male leadership and orientation of its institutions. British scholars in the late nineteenth and early twentieth centuries commenced the 'first wave' of scholarship on women in Buddhism. C.A.F. Rhys Davids (1857–1942), Bimala Churn Law (1862–1969), and Isaline Blew Horner (1896–1981) were textual scholars who studied the role of women in Buddhism and proposed that women played definitive roles in Buddhist history and Pāli literature embodied and produced a remarkable degree of religious egalitarianism. In accordance with early Western scholarship on Buddhism, they prioritized texts and consulted primary sources (e.g., the Pāli canon) to locate their subject of study. These pioneering studies championed Buddhism as emancipatory for women in contrast to the (perceived) oppressiveness of the Brahmanical culture in which it arose. Brahmanism's own developments and advances vis-à-vis women's status and representation during the period of Buddhism's inception did not receive scholarly attention. By and large, Buddhism was deemed liberating for women and inherently egalitarian because it allowed women to renounce the subordinate, socially conditioned roles of wife and mother and to assume the gender-free spiritual path of the monastic. Any discrimination or sexism within Buddhist textual and institutional structures was attributed to foreign imposition (i.e., seen as a residue of traditional Indic conceptions of women), propositions that are widely disputed in Buddhist Studies today.

The 'second wave' of scholarship grew out of the Women's Liberation Movement and feminism of the 1960s and 1970s. Equipped with the language, rhetoric, conceptual frameworks, and institutional advances spawned by the feminist movement, a new cohort of Buddhist scholars revisited the work begun by their predecessors (Murcott, 1991; Blackstone, 1998). Many of these scholars observed evidence of egalitarianism in Buddhism and upheld the essential teachings of Buddhism as incompatible with gender hierarchy and discrimination against women (Minamato, 1991; Carmody, 1991; Gross, 1993). Sexist or discriminatory elements in the Buddhist record were seen as cultural accretions or later accumulations on an originally egalitarian core. Similarly, some scholars differentiated between two levels of Buddhist teachings – the core teachings of Buddhism which are free from gender bias (and thus the springboard for feminist collaboration) and the mundane level of teachings which are affected by social context and thus amenable to varying manifestations of gender discrimination (Kabilsingh, 1991). Other scholars have located a 'new' egalitarian Buddhism, replete with women leaders and teachers, in the convert communities and Dharma centers established in America since the 1960s (Friedman, 1987; Boucher, 1988; Dresser, 1996). Recreating Buddhist institutions free from hierarchy, gender inequity, and sexism has also been the concern of Asian Buddhist immigrants in Western contexts (Gregory and Mrozik, 2008: p. 12). 'Second-wave' scholarship tended to hierarchize Buddhist schools and periods in terms of their positive or negative attitudes toward women. Later developments of Buddhism, namely the Mahāyāna traditions, were seen as increasingly egalitarian and emancipatory for women in contrast to the (perceived) conservatism and sexism of early Indian (equated with Theravāda) Buddhism. Many studies focused on images of women in Mahāyāna texts, revered female figures in Tibetan Buddhism, and feminine symbolism in Buddhist Tantra (Paul, 1979; Klein, 1995; Shaw, 1994). Critics note that the characterization of Mahāyāna as 'pro-women' overlooks vicious tirades against women in Mahāyāna texts (Wilson, 1996: pp. 7, 8), dismisses positive characterizations of women in Theravāda Buddhism (Lang, 1986: p. 64), and displaces the Brahmanical-Buddhist continuum of earlier

scholarship onto a Theravāda–Mahāyāna continuum – in which Mahāyāna is championed primarily for not being Theravādin (Walters, 1994: pp. 361, 362). Resisting the tendency to view Buddhist schools and periods as uniformly or univocally 'pro-women' or 'anti-women,' prominent scholars recognize a diversity of voices in Buddhist texts, leading to varied outcomes, such as inclusive salvation (androgynous or egalitarian), institutional androcentrism, and misogynistic asceticism (Sponberg, 1992).

The 'third wave' of scholarship on women in Buddhism is heavily informed by poststructuralist and postcolonial theory, gender and queer theory, men and masculinities studies, and third wave feminism. Studies in this most recent wave seek to take women's subjectivity seriously and to construct interpretive models of representation that at once privilege indigenous perspectives and engage in critical analysis. Some studies employ ethnographic research and focus on women's experiences in very specific Buddhist contexts and localities (Arai, 1999; Brown, 2001; Gutschow, 2004; Falk, 2007). Other studies have shifted from 'women' to 'gender' as the subject of investigation (recognizing that both women and men are impacted by gender roles and 'perform' gender), including the examination of men and masculinities in Buddhism (Faure, 2003; Powers, 2009). Still other studies are beginning to explore the complexity of gender identities, particularly those identities that fall outside of the male/female polarity (Gyatso, 2003). Works by Cabezón (1992, 1998), Zwilling (1992), Schalow (1992), and others have also established queer theory as a dynamic field of inquiry for scholars and practitioners of Buddhism.

The varying strategies and approaches of scholars attest to the diversity of women's images, roles, experiences, and concerns in different Buddhist contexts. These varied methodologies and assessments also demonstrate that "the history of Buddhism is made to reflect the concerns of the scholars reconstructing it" (Wilson, 1996: p. 7).

Women in Early Buddhism

In Pāli scriptures, the path espoused by the Buddha as most conducive to the attainment of *nirvāṇa* is the path of renunciation, referred to as 'going forth' from home to homelessness. 'Going forth' involves renunciation on three levels: first, physically renouncing the home, that is, leaving the householder life to pursue the monastic life; second, psychologically renouncing the home, that is, leaving behind desire and attachment; and third, ontologically renouncing the home, that is, leaving *saṃsāra*, the cycle of death and rebirth characterized by suffering (Collins, 1982: p. 169). A key concern of early Buddhists was whether women can, or should, renounce the home and 'go forth' into the monastic life. Buddhist texts voice apprehension about the appropriateness of women renouncing the world (particularly leaving the home and family and eschewing the roles of wife and mother) and doubt regarding the possibility of women cultivating detachment and dispassion. At the same time, women's spiritual capacity is acknowledged and women are regarded as ontologically equal to men in matters of the *Dharma* (the Buddha's teachings). In the well-known Pāli account of the founding of the community of Buddhist nuns (*bhikkhunīs*), the Buddha permits women into the monastic order, citing women's ability to realize the highest Buddhist goal of liberation. Early Buddhist literature affirms women's capability of attaining *nirvāṇa* (and other spiritual goals) and provides many examples of highly accomplished female devotees in meditation, morality, and wisdom. Most notably, the *Therīgāthā* (*Verses of the Elder Nuns*), the enlightenment poetry of the early Buddhist nuns, documents the spiritual achievements of women and their ability to assume spiritual authority from Buddhism's inception. The *Therīgāthā* is the only work in the Pāli canon attributed to the authorship of women and comprises the oldest known collection of women's literature. The position of the nun is further strengthened by the early Buddhist concept of the fourfold society. According to Buddhist scriptures, the Buddha sets forth the prescription for an ideal Buddhist community replete with four assemblies: monks, nuns, laymen, and laywomen. All four divisions are seen as essential to the well-being of the religion and are said to 'illuminate the Order' (*Aṅguttara Nikāya*).

This optimistic view of renunciant women is curbed by the Buddha's proclamation that the creation of an order of nuns will dramatically hasten the decline of his teachings in the world. Moreover, as a condition for their ordination, renunciant women are obligated to observe Eight Heavy Rules (*Garudhammas*), with the first rule requiring a senior nun to bow down before a monk ordained even one day. The Eight Heavy Rules are highly controversial on two fronts. First, they clearly attempt to relegate women to a subordinate role. Second, the historicity of the Eight *Garudhammas* is questionable. Evidence suggests that the Eight Heavy Rules were formed after the establishment of the nuns' order and, as later interpolations (whether in the Buddha's lifetime or in later centuries), were interjected into the founding story of the *bhikkhunī* order. Beyond the *Garudhammas*, nuns are required to observe more precepts than monks as set forth in the monastic code of discipline (*Vinaya*). Whether more precepts necessarily translates into sexist discrimination has been thrown into question by those who see these rules as operating on women's behalf and for women's protection, and as consistent with an affirmation of the spiritual equality of women and men (Chung, 1999: p. 45). Nonetheless, the male gender is consistently hierarchized above the female gender in early Buddhism.

Early texts confer women's ability to attain the status of an *arhat* (one who has attained enlightenment). However, they are more ambivalent about other spiritual attainments. According to the list of women's 'five hindrances' which appears repeatedly in Buddhist sources, a woman cannot occupy the position of 'Buddhahood,' among four others, in the cosmos. Thus, in the early tradition, Buddhas are never female. While the *Jātakas* testify to the myriad incarnations of the Buddha in previous lives, including animal forms, female corporeality is conspicuously absent. To a large degree, the decided maleness of the Buddha stems from the pan-Indian notion of the 32 Marks of a Great Man (*Mahāpuruṣa Lakṣaṇa*), including the mark of having a penis concealed in a sheath. It must be noted here that the indisputable affirmation of women's ability to attain *nirvāṇa* probably held much greater significance than

women's exclusion from Buddhahood since early Buddhist sources stress enlightenment as the only feasible goal.

Gender is arguably irrelevant in matters of spiritual pursuit. Monks (*bhikkhus*) and nuns (*bhikkhunīs*) follow the same path to the same liberation. Birth in a male or female body neither abets nor hinders spiritual accomplishment: "Whoever has such a vehicle, whether a woman or a man, shall indeed, by means of that vehicle, come to nirvāṇa" (*Saṃyutta Nikāya*). Indeed, the *Dharma* appears to be 'gender-free.' The classic Buddhist doctrine of *anātman* (Pāli, *anattā*) – frequently translated as 'no soul,' 'no self,' or 'egolessness' – is common to all forms of Buddhism and has strong implications for gender analysis. If there is no permanent self or soul attached to an individual's existence, then there cannot be any permanent, real, or lasting identity based on gender. Early Buddhist texts recognize the fallacy of clinging to gender identities and distinctions, as evidenced in the *Saññoga Sutta* which suggests that attachment to gender identity is a form of bondage. Likewise, in the *Soma Sutta*, the *bhikkhunī* Soma links gender discrimination to the work of Māra and gender neutrality to the realization of *anātman*. The Pāli canon suggests that the very concept of gender differentiation can serve as a hindrance to attaining enlightenment.

The Buddhist adulation of 'genderlessness' mirrors the early Buddhist myth of the origin of society found in the Pāli *Agañña-sutta* (*Knowing the Beginning*). This cosmogony depicts a Golden Age where identical, asexual, ethereal beings dwell blissfully in the heavens. Upon becoming greedy for food, they begin eating and gradually become more corporeal and grosser in form, ultimately differentiating into male- and female-sexed beings. The emergence of the sexes leads to further moral degeneration in the form of passion, lust, and jealousy. Androgyny and asexuality characterize the once perfect state of blissful luminosity and, in effect, Buddhist monastics seek to return to this genderless, passionless ideal. In terms of appearance and behavior, Buddhist monks and nuns exercise androgyny with shaven heads, baggy robes, and identical lifestyle. Likewise, one of the most important distinguishing characteristics of monks and nuns is that they are celibate. For male and female monastics alike, transgressing the vow of chastity is an offense that carries the penalty of expulsion. While there is a tendency toward androgyny and soteriological equality, gender is not obsolete on the Buddhist path. According to the Pāli canonical texts, proper male and female gender must be officially confirmed at the time of ordination and ambiguously gendered or inter-sexed persons are banned from entering the *Saṅgha* (monastic community).

A widespread Buddhist belief echoed in early texts is that being born a woman is the result of bad karma. Buddhist scriptures articulate the woes of female incarnation, including "leaving relatives behind to go to a husband, menses, pregnancy, giving birth and having to wait upon a man" (*Saṃyutta Nikāya*). It is debatable whether these judgments are evidence of misogyny or evidence of the adverse conditions under which women lived. Either way, while women are often depicted aspiring to be reborn as men (and succeed in achieving this 'higher' rebirth by performing meritorious acts), the men of Buddhist lore never express the desire to be reborn as women (though they sometimes incur a female rebirth as a result of bad deeds). This popular and long-standing attitude persists in some Buddhist cultures today. This ethos of female inferiority has adversely affected the order of nuns throughout history. Because nuns are regarded as lesser 'fields of merit,' lay donors prefer to give alms to monks to accrue more merit. Recent data, however, suggests an improved situation for Buddhist renunciant women, including increased institutional support and wider recognition as worthy religious persons by monks and laity (Seeger, 2009).

The relevance or irrelevance of gender is further complicated by the constraint of male celibacy and the threat women pose to this celibacy. Certain texts of the Pāli canon attribute to women an uncontrolled sexual appetite and inherent licentiousness. Women are further characterized as uncontrollable, envious, greedy, and weak in wisdom (*Aṅguttara Nikāya*). A particularly salient image is that of woman as temptress. Buddhist texts attribute inordinate sexual (and destructive) powers to women. Women are described as 'snares of Māra' (*Aṅguttara Nikāya*) and members of the *Saṅgha* are advised to 'keep wide awake' in the face of feminine wiles (*Dīgha Nikāya*). Women's beauty holds men in thrall and leads wayward monks astray; to avoid temptation monks are instructed to contemplate the transience and foulness of the female body. Just as the allure of the female form threatens men's spiritual progress, so attachment to one's own beauty is an obstacle to women on the spiritual path. 'Vain nuns' like Rūpa Nandā of the *Therīgāthā* are described as being intoxicated with their own beauty and having 'fierce affection' for their bodies. Enlightenment can only be achieved by contemplating the impurity and impermanence of the female body, often one's own. In canonical and commentarial texts, women's bodies and bodily processes are described as polluted and defiling much more frequently than are men's, and women are not depicted contemplating horrifically transformed, disfigured, dead, or sleeping male bodies (Lang, 1986; Wilson, 1995, 1996; Blackstone, 1998).

Analyses suggest that women tended to fare better as models of lay practice (versus monastic practice), particularly as supporters and nurturers of the Buddhist tradition (Willis, 1985). Some scholars posit that the exaltation of laywomen parallels the declining status of *bhikkhunīs* (Paul, 1985: p. 79). Others conjecture that laywomen are presented much more positively than nuns in Buddhist stories because laywomen conform to socially prescribed female roles (Allione, 1986: p. 8; Falk, 1980: p. 222; Neumaier-Dargyay, 1995: p. 164). Viśākhā, the most lauded woman in the Pāli texts, is commended for her immense generosity, unwavering piety, knowledge of the *Dharma*, unsurpassed beauty, and abundant fertility. While lay-benefactors like Viśākhā figure prominently and positively in early Buddhist literature, other laywomen are portrayed negatively: namely, wives trying to regain their monastic husbands (e.g., the story of Sudinna in the *Vinaya Piṭaka*), mothers mourning the loss of their sons to the renunciant life, and beautiful women presenting themselves as sexual obstacles to abstinent monks. On the one hand, the scriptures praise laywomen, as when the Buddha of the *Etadagga-vagga* commends 10 laywomen for their qualities – among them being learned, developing loving kindness, exhibiting undivided pleasantness, attending to the sick, and reaching the *jhanas* (meditative states). On the other hand, Buddhist texts warn monks against the

filial and social obligations that entrap the householder. Interestingly, nuns are oft depicted voicing welcome emancipation from domestic drudgery and filial duties.

Women in Mahāyāna Buddhism

Mahāyāna Buddhism, which began to develop about 500 years after the Buddha, expounded upon earlier Buddhist doctrines and heralded new ideas regarding women and gender ideology. The wide range of attitudes toward women (as described above) in early Buddhism continues to be found in later Mahāyāna traditions. It has been suggested that Mahāyāna revalorized the female gender and that the religious ideals of universal salvation, emptiness, and undiscriminating wisdom signaled greater (or renewed) openness to women and a more equitable sociopolitical order. However, there is no substantial evidence indicating that women fared better in Indian Mahāyāna Buddhism than in the mainstream tradition. This, of course, points to the broader issue of distinguishing between symbolic representation and flesh-and-blood reality, as well as between textual materials and the practical religion of people at large.

With the advent of Mahāyāna came a new religious goal: that of becoming a *Bodhisattva* (and eventually a Buddha). In contrast to the earlier ideal of the *arhat*, the *Bodhisattva* (literally, 'enlightenment-being') vows to remain in *saṃsāra* to work for the complete enlightenment of all sentient beings. As an immensely compassionate being, the *Bodhisattva* postpones his or her enlightenment but is destined in the future to become a Buddha. The *Bodhisattva* path is open to both men and women, and all Mahāyānists are encouraged to pursue it. Mahāyāna texts are noted for their gender-inclusive language and sūtras are frequently addressed to 'good sons' and 'good daughters' of the *Dharma*. However, while the 'good son' is often addressed independently, the 'good daughter' is usually addressed in association with the 'good son.' Nonetheless, the view of the good daughter is decidedly optimistic. According to the *Lotus Sūtra*, the good daughter is capable of awakening to the thought of enlightenment, receiving a prediction of Supreme, Perfect Enlightenment, and teaching the *Dharma*, among other feats.

While the *Bodhisattva* ideal appeals to the masses and points to the universal availability of enlightenment, the path of the *Bodhisattva* is understood to be strenuous and to require an enormous span of time over many rebirths. There is disagreement among Mahāyāna texts as to what level of *Bodhisattvahood* a woman can attain in female form. Some sūtras deny women's entrance in Buddha-lands, while others accept women as lower-stage *Bodhisattvas*; still others accept women as advanced *Bodhisattvas* and imminent Buddhas. The *Pure Land Sūtra* (*Sukhāvatīvyūha*), for example, dictates that one must be a male in order to be born in the land of Amitābha, implying that a woman must wait for another existence as a man in order to progress on the *Bodhisattva* path. In contrast, many Mahāyāna sūtras describe virtuous and capable women who may become *Bodhisattvas* and even Buddhas in current lives, which were begun as female. Employing a narrative theme known as the 'transformation of sex' (*parivṛttavyañjana*), these texts open up the possibility of a woman attaining *Bodhisattvahood* or Buddhahood in this lifetime by undergoing sexual change. Transformation of sex sūtras follow a typical narrative pattern. A debate over the spiritual capabilities of women ensues between a wise and eloquent woman (a *Bodhisattva*) and a highly respected male elder (often a monk-hero or *Bodhisattva*). Responding to the challenge posed by the man that a woman cannot (in her female form) attain Buddhahood, the female *Bodhisattva* instantaneously changes her sex and transforms into a man (prior to immanent Buddhahood). In some transformation of sex sūtras, such as the *Vimalakīrtinirdeśa-sūtra* (*Discourse on the Teaching of Vimalakīrti*), the female protagonist engages in a playful display of illusion and ultimately refuses to transform her sex on the basis that such distinctions are illusory and empty of any inherent reality. These texts have been interpreted in a variety of ways. It has been suggested that sexual transformation represents a symbolic transition from a state of imperfection and attachment to sensual existence (represented by the female body) to a state of mental perfection, desirelessness, and eventual enlightenment (represented by the male body) (Paul, 1979). Others contend that the significant point is not that the woman becomes a man, but rather that the woman had already become a *Bodhisattva* and had already made her resolution to attain Buddhahood while in her female form, thus equipping her with the power to change her sex (Gross, 1993). Still others analyze the Mahāyāna sex-change sūtras through the lens of poststructuralist feminist theory and view the transformation of sex episodes as theatrical testaments to the fluidity and performativity of gender (Owen, 1997). Notably, it is always women who transform (or refuse to transform) into men; men are never depicted transforming (or being challenged to transform) into women – indeed, it appears this would be unthinkable.

To complicate the matter further, some Mahāyāna texts state that womanhood and Buddhahood are mutually exclusive. In other words, a Buddha will never appear in female form and a woman cannot be a Buddha. In the *Lotus Sūtra*, one of the most popular and influential Mahayana texts, Śāriputra tells a young woman (the Nāga princess) that she cannot possibly achieve her goal of Supreme, Perfect Enlightenment because women cannot realize five types of status, among them the status of an irreversible *Bodhisattva* (and implicitly a Buddha). The possibility of female Buddhas is clearly a vexing issue. With regard to a female Buddha, the Mahāyāna texts do not explicitly name any. Nonetheless, the Mahāyāna tradition depicts female *Bodhisattvas* of the most advanced order, such as Tārā and Kuan-yin, both of whom are the objects of major worship and veneration cults. Queen Śrīmālā "Who Had the Lion's Roar (of a Buddha)" (*Śrīmālādevīsiṃhanāda-sūtram*) comes closest, perhaps, to an implied image of female Buddhahood. According to this sūtra, Queen Śrīmālā converts many to Buddhism, is praised for her wisdom and compassion, eloquently expounds the *Dharma*, and receives the prediction that she will become a Buddha. The level of *Bodhisattvahood* which she represents became the subject of many subsequent commentaries. Some suggest Queen Śrīmālā was an irreversible *Bodhisattva*; others claim she was really a male appearing as a female; yet others demote her to a first-stage *Bodhisattva*. Like the discrepancies over Queen Śrīmālā's status, the question of whether women were ever recognized

as potential or imminent Buddhas, remains unanswered (Paul, 1979).

The personification of the 'Perfection of Wisdom' (*Prajñāpāramitā*) as feminine emerges as another oft-cited 'pro-female' feature of Mahāyāna. *Prajñāpāramitā* is worshipped as a female goddess and extolled as 'the mother of the Buddhas' (since Buddhas are born from wisdom). Some claim that she owes her femininity to a grammatical coincidence since the Sanskrit word for wisdom, '*prajñā*,' takes the feminine gender. Whether accidental or deliberate, the pursuit of wisdom – personified as female – has been the subject of much Buddhist art and has developed into a major metaphor and spiritual discipline in Mahāyāna and Vajrayāna Buddhism. The female *prajñā* (often symbolized by a lotus or a ritual bell) is typically paired with the male *upāya*, a masculine noun meaning 'compassionate skillful means' (often symbolized as a *vajra* or thunderbolt). The attainment of perfect enlightenment rests on the symbolic union of these two complementary forces. Tantric Buddhism, in particular, explicitly envisions Buddhahood as the perfect integration of these male and female energies. Visually, this is often depicted by male Buddhas and *Bodhisattvas* in sexual union with female consorts, also known in Tibetan as *yab–yum* ('father–mother') images. This highly sexual gender symbolism is unique to Tantric philosophy and practice, and it has received accolades as a dramatic valorization of the feminine as well as condemnation as the sexualization of women for the spiritual advancement of men.

The Contemporary Buddhist Women's Ordination Movement

A major issue for Buddhist women today is the status of women in Buddhist monastic institutions. The order of fully ordained nuns (Pāli: *bhikkhunī*, relevant to Theravāda Buddhists; Sanskrit: *bhikṣuṇī*, relevant to Mahāyāna and Tibetan/Vajrayāna Buddhists) is not uniformly present in Asian Buddhist settings. Currently, women can be ordained as *bhikṣuṇīs* in the Mahāyāna traditions of China, Korea, Taiwan, and Vietnam as well as in Chinese diaspora communities in countries such as Indonesia, Malaysia, and the Philippines. However, the *bhikṣuṇī* category is not available to women in the Tibetan/Vajrayāna traditions of Bhutan, the Indian Himalayas, Mongolia, Nepal, and Tibet (Mrozik, 2009). Likewise, women have been barred from *bhikkhunī* status in the Theravāda traditions of South and Southeast Asia, until recent developments. Largely in response to these status disparities and the unequal treatment of female Buddhist renunciates, an international Buddhist women's movement has emerged (hereafter referred to as the '*bhikkhunī* movement'). Broadly speaking, the *bhikkhunī* movement seeks to revive the lineage of Buddhist nuns where it has been broken, to reinstate the *bhikkhunī* order where it has died out, and to introduce the community of Buddhist nuns where it has been absent. Founded in 1987, Sākyadhitā: International Association of Buddhist Women has been instrumental in the global *bhikkhunī* movement. Sākyadhitā international conferences bring together scholars, practitioners, and activists with the aim of promoting gender equity in Buddhism and equal opportunities for education and training for Buddhist women worldwide. Though the *bhikkhunī* movement has been critiqued as a western feminist imposition, attempts have been made in Theravāda countries to revive the *bhikkhunī* order, from the early twentieth century up to the present day.

The Pāli canon recounts that the Buddha allowed women to be ordained into the *Saṅgha* and history attests to a thriving order of *bhikkhunīs* on the Indian subcontinent and beyond. However, the Theravāda *bhikkhunī* order vanished some 1000 years ago. While Sri Lanka is generally regarded as the only Theravāda country where a *bhikkhunī* order once flourished (the order of nuns appears to have lapsed in Sri Lanka in the eleventh century), scholarship suggests that *bhikkhunīs* existed in the Theravāda country of Burma until about the thirteenth century (Kawanami, 2007). There is no evidence pointing to any *bhikkhunīs* in Thai history, though isolated attempts have been made in the past to establish the order. Overall, it is widely believed that *bhikkhunīs* never existed in all of Southeast Asia. On both local and international levels, there is an ongoing controversy over the possibility of reviving the vanished ordination lineage of Theravāda nuns. This controversy hinges on the legitimacy of Higher Ordination (*upasampadā*) for women, an ordination which confers the status of '*bhikkhunī*.' According to traditionalist readings of the Pāli *Vinaya*, a female ordinand must seek Higher Ordination from a dual *Saṅgha*, that is, from the *bhikkhunī Saṅgha* and the *bhikkhu Saṅgha*. In the absence of an existing *bhikkhunī Saṅgha*, proper ordination cannot be granted.

There are a multitude of arguments for and against the revival of the Theravāda *bhikkhunī* lineage. Representative arguments for 'pro-revivalists' include: the Buddha's example of ordaining women; the Buddha's prescription for a fourfold society, of which *bhikkhunīs* are an essential component; the doctrinal premise of the equal potential of women and men to attain enlightenment; and various appeals to the secular ideals of human rights and religious freedom. Representative opinions of 'anti-revivalists' include: the illegitimacy of reinstating the Theravāda *bhikkhunī* lineage via a dual ordination procedure that involves Mahāyāna *bhikṣuṇīs*; adherence to the official teaching that once extinguished, the *bhikkhunī Saṅgha* cannot be revived; the corollary belief that only a perfectly enlightened Buddha (and implicitly the next Buddha) can reconstitute a broken *bhikkhunī Saṅgha*; and opposition to changing or manipulating the training rules outlined in the *Vinaya*.

What is perhaps most interesting is how Theravāda Buddhist women have responded to this challenge. Chatsumarn Kabilsingh, a leading proponent of the *bhikkhunī* movement in Thailand, took Higher Ordination in 2003 outside her native Thailand in Sri Lanka and became *Bhikkhunī* Dhammanandā. To fulfill the dual-*Saṅgha* ordination rule and revive the *bhikkhunī Saṅgha*, Dhammanandā advocates that female ordinands turn to Chinese nuns of the uninterrupted Dharmaguptaka lineage to orchestrate *upasampadā*. Critics, however, question the legitimacy of 'cross- *Saṅgha* ordination'

and the intactness of the ordination lineage (Seeger, 2008). Apart from religious matters, many perceive the *bhikkhunī* lineage as foreign and 'non-Thai.' Moreover, many religious women do not want to follow in Dhammanandā's path and prefer to practice Buddhism in ways that are more commonly recognized and accepted in their local communities. Overall, the *bhikkhunī* movement has enjoyed greater success in Sri Lanka (however not without controversy), in large part because a *bhikkhunī* lineage is part of Sri Lankan history, can be perceived as local, and appeals to issues of national and ethnic identity (Mrozik, 2009).

In Thailand, Burma, Sri Lanka, and other traditionally Theravāda countries, women have pursued the renunciant life even though the *bhikkhunī* lineage has died out or been altogether absent. New categories of female renunciation have emerged in these societies and have persisted for several centuries: namely the *mae chis* of Thailand, the *thilashin* of Burma, and the *dasasilmātās* of Sri Lanka. Though each is distinctive, these alternative forms of renunciation share common features. They observe eight to ten precepts, shave their heads, don monastic robes (of varying colors), and observe celibacy. Concerns about these alternative renunciant institutions include: their liminal status between lay and monastic forms of practice (Jordt, 1988; Falk, 2000); their marginalized, unsupported, and extremely low status (Kabilsingh, 1991); their valuation as a poor substitute for the *bhikkhunī* ideal (Tomalin, 2006); and doubt as to whether they can factually or potentially be real alternatives to the missing *bhikkhunī* order (Seeger, 2009). Many of these renunciant women are not 'interested' in becoming *bhikkhunīs* (Battaglia, 2007; Falk, 2007; Kawanami, 2007). Reasons for resisting *bhikkhunī* ordination include doubts about lineage purity, and the validity of the ordination procedure; concern that attaining *bhikkhunī* status would place nuns more strictly under the control of the *Saṅgha*; skepticism that the *bhikkhunī* role is viable or necessarily carries more social or spiritual efficacy; fear of social censure and loss of lay support; and allegiance to their own categories of renunciation as worthy and legitimate. The fact that some women in these alternative orders do not want full ordination or do not staunchly support the revival of the *bhikkhunī* lineage is a source of tension in the contemporary *bhikkhunī* movement.

This is a particularly germane time for the study of women in Buddhism. Myriad visions of female religiosity gain recognition and momentum, particularly with the prominence of global Buddhist–feminist networks, the role of the internet and digital devices in information dissemination and accessibility, and the increasing scholarship and print-media devoted to female practitioners of Buddhism and Buddhist women's communities. It remains to be seen how the *bhikkhunī* movement will play out in Southeast Asia and beyond, and how the continued involvement of women will change the face of Buddhism, both locally and globally.

Abstract

In Western societies, women are consistently shown to have stronger religious beliefs and engage in religious participation and devotion more frequently than men. Sociologist and psychologists have explored several possible explanations for these differences, including women's higher levels of family involvement, lower rates of labor force participation, higher rates of deprivation, and greater health risks earlier in life due to childbirth.

In Western societies, women are more religious than men on every measure of religiosity. Why this should be has become a major interest of sociologists of religion. Yet, the sociology of religion only belatedly included gender on its agenda (Woodhead, 2000), and feminists have been more concerned with why there are so few women in the priesthood than with why there are so many in the pews. Scholars have also been concerned with documenting the historical patriarchal stance of Christianity, the pre-Christian spirituality of women, and the spirituality of hitherto ignored but highly gifted individuals, rather than documenting the ordinary religiosity of millions of churchgoing women. Feminist theories that religion is bad for women need to come to terms with, but in fact often ignore, women's opting for formal religion in greater numbers than men. This article reviews the possible explanations for women's greater religiosity, focusing particularly on mainline churchgoing in the West in the twentieth century.

Data

Whether it is a matter of churchgoing, private prayer, or the content of religious belief, women appear more religious than men, and have been for at least 200 years (Douglas, 1978). Within Western Christianity, mainline churches demonstrate the greatest fall off in attendance by men; independent, Pentecostal, and orthodox churches have been able to resist the trend. The extent to which secularization is caused by men reducing religious observance more than women varies by country (Woodhead, 2000; Freese, 2004).

The dimension of religious life where the difference between women and men is biggest is private devotion – prayer and Bible reading. This raises the question whether men engage in religious practices when they are publicly acceptable or even required, but tend not to bother with private devotions when there is no social pressure. It is possible that secularization, defined as the decline in the social importance of religion, tends at the same time to lead to religion's feminization. Islam and Judaism, in which religion is still part of public life, involve men more than women in public worship. Studies in the West have also focused on how men's irreligiosity may be a function of their inherent tendency to engage in more risky behaviors (Miller and Hoffmann, 1995; Miller and Stark, 2002; Freese, 2004).

Independent of degree of belief, what men and women believe differs. Women, if they are asked to describe the God in whom they believe, concentrate rather more on a God of love, comfort, and forgiveness, while men tend to refer to a God of power, planning, and control (Walter and Davie, 1998).

Material and Social Deprivation

Neo-Marxist deprivation compensation theories see religion as a way in which oppressed people cope with their misery and suffering. If, as feminists argue, women are more oppressed than men, we would expect more women than men to turn to religion. There certainly are examples of this, especially, in the early periods of industrialization both historically in the West and in less-developed societies. In advanced industrial societies, however, there is less evidence for this theory of female religiosity, religious participation being related to parenthood and employment status rather than to measurable indices of gendered deprivation.

Lack of Status

Women's systematic exclusion from better paid jobs, from political office, and from other parts of the public world has reduced their social status. Christianity's proclamation that God loves every individual equally may be more immediately attractive to those who are not accorded respect in society. Once inside the church, however, women may find themselves even more deprived of status and power vis-à-vis male members. Yet women remain in greater numbers than men. Ozorak (1996) found that many women valued their churches for the social and emotional support, which existed irrespective of their exclusion from formal power; for those more concerned with connection and relationship than with hierarchy and power, the female fellowship of the church empowered them even though the office-holding men monopolized the glory.

Conservative churches and synagogues that emphasize traditional gender roles within the family appeal to many women: they provide status for the wife and mother, and provide hope that conversion may turn men into responsible husbands and fathers.

Guilt

A number of psychological studies show that women experience more guilt feelings than men. If one of the main purposes of Christianity is to assuage guilt, then we would expect it to attract those who feel a need for forgiveness. Some churches actively foster guilt feelings, which they then offer to resolve. Churches have often portrayed women as more guilty, more profane, than men. Much of this is linked to sexual guilt and a double standard enforcing women's chastity. Insofar as Christianity induces guilt, we may say that religion not only compensates for a societally created deprivation of status and self-respect, but actually fosters the very deprivation that it then compensates for. This is perhaps the nearest to a feminist theory of why women should be attracted to a religion that oppresses them. Though there is considerable historical evidence of this process, and studies show that members of exclusivist sectarian groups express negative views of nonmarital sexuality even though members often engage in premarital, extramarital, and homosexual relations (Sherkat, 2014).

Birth and Child Rearing

Religion is supposed to provide comfort against anxiety and existential terror; psychological studies point out that women generally have higher levels of fear than men (Miller and Hoffmann, 1995; Miller and Stark, 2002). This could be related to their more direct involvement in the inherently scary businesses of birth and death and their day-to-day responsibility for child rearing (Sherkat, 2008). Men have comparable familiarity with sickness and death only on active service during wartime – a time when they may be more likely to turn to religion. There have been very few studies into the spirituality of childbirth, so it is too early to say whether experiencing the 'miracle' of birth accounts in part for female religiosity. Much more research has been done into religiosity in relation to child rearing. The general pattern is that having children to look after raises men to the religious level of women; it is possible that the vulnerability and dependency of young children raises religious issues that men can normally avoid. It is, therefore, parenthood, not motherhood, that raises questions of existential anxiety and a desire to involve children in religion.

Workforce Participation

A major thread in theories of secularization is that the more people are immersed in the institutions of modernity, notably by working for bureaucratic and or capitalist organizations, the more secular they are likely to become. Women who stay at home are, therefore, protected from the secularizing influence of the modern marketplace. This hypothesis (classically formulated by Luckmann) has led to a number of empirical surveys aiming to determine whether, and if so why, women who go out to work are less religious than those who stay at home.

The findings of these studies vary by country. Taking a paid job in, for example, Australia where there is a secular ethos in the workplace is likely to have a more secularizing effect than taking a job in the American Bible Belt. Since both data and hypotheses remain inconclusive, a constructive avenue of research might be to look at the type of paid work done by women. Women's paid work is far more likely than men's to be of a caring nature, involving skill in interpersonal relations and 'emotional labor.' If what protects women (and some men) from the secularity of modernity is not family life but interpersonal care, then those employees engaged in caring work should be compared with those engaged in other kinds of work. If research were to confirm that women paid to care are more religious than those paid to do other things, we would still be left with a puzzle: are they more religious because the caring nature of the work protects them from secularity, or do they enter caring work because they were more religious to start with?

An Ethic of Connection

Gilligan (1982) considers that women operate according to a flexible ethic of compassion and connection rather than abstract justice. Woodhead (2000) has used this insight to critique the 'privatization thesis,' namely that in an alienating, plural modern world, people retreat to the private sphere where they find identity, meaning, and perhaps religion. She suggests that this thesis makes sense from a male perspective, but women are less involved in the alienating public sphere. For them, religion has less to do with providing meaning and more to do with articulating the social relationships. Traditional churches do this by encouraging the family, but they can also encourage other kinds of relationships. A religion whose founder emphasized love and compassion is more likely to appeal to Gilligan's women. Indeed, male clergy have often struggled to make Jesus appeal to masculine men, and research has shown that gay men are relatively religious when compared to heterosexual men or lesbians (Sherkat, 2002). This is echoed in Thompson's (1991) finding that what is correlated with Christian religiosity is not gender but a 'feminine' worldview, that is, one that is affectionate, sympathetic, sensitive to the needs of others, eager to soothe another's feelings, tender, and loving toward children.

Death

The extent to which religion is a way of helping humans deal with death has been extensively debated. What is clear is that women encounter death disproportionately as carers, and also as mourners. In the times of high infant mortality, women may have been more affected than their husbands by the deaths of their children, though men were more likely than women to lose a spouse – as nineteenth-century gravestones bear ample witnesses. Today, with women living longer than men and marrying younger, wives are very likely to outlive their husbands. Spousal bereavement is now a much more common experience for women than for men. Whether or not this helps to explain women's greater religiosity, it seems very likely to lie at the root of the most common form of afterlife belief in the modern West, namely a belief in reunion with loved family members. Women who place a high value on personal relationships are unlikely to give them up when death intervenes, and this may possibly account for women being more likely than men to experience the presence of one who is dead. Life

after death is central to Christianity, and insofar as women have a greater interest in there being life after death, we may postulate that some women's religiosity may be rooted in their experience of death and bereavement. On the other hand, it may be the other way around – that more women than men believe in life after death simply because of their general religiosity.

Women's Status and National and International Security

Valerie M Hudson, Texas A&M University, College Station, TX, USA

Abstract

Until the turn of the twenty-first century, mainstream scholars and professionals in national and international security have not viewed the well-being and security of women as important. Empirical literature has emerged, which demonstrates that this linkage is significant. This article surveys the literature, examining in particular issues of war, peace, and stability of nations in relation to women's status and security.

Introduction

The study of national and international security has historically centered on relations between governments and particularly on the prevention of great power war. It has traditionally included topics such as the causes of war and war termination, empires and world order and has expanded in more recent decades to include study of civil wars, humanitarian intervention, and other issues.

Notably lacking in most literature in Security Studies is attention to women's security and the role of women in promoting security. And yet, in the policy-making community, we hear statements by world leaders that there is a strong relationship between the situation and security of women, on the one hand, and the security of the nations in which they live. For example, in 2010, then-Secretary of State Hillary Clinton asserted that, "the subjugation of women is a direct threat to the security of the United States" (AFP, 2010). In 2006, then-Secretary General of the United Nations, Kofi Annan, opined, "The world is starting to grasp that there is no policy more effective in promoting development, health and education than the empowerment of women and girls. And I would venture that no policy is more important in preventing conflict, or in achieving reconciliation after a conflict has ended" (Annan, 2006). What does the social science literature tell us about the relationship between the security of women and national and international security?

First a note on the measurement of the security and well-being of women. There are two primary approaches to such measurement. One is to measure the difference between men and women on measures deemed important to security and well-being. So, for example, one might examine the difference in years of schooling between men and women within a society, or the difference in the representation of men and women in national legislatures. These measures are often characterized as measures of 'gender equality' or 'gender inequality'. Other studies use direct measures of the level of the security and well-being of women. For example, researchers might use the prevalence of rape and sexual assault against women in a society to examine women's physical security. Both approaches are justifiable, and the type of measure used will typically be noted in the survey below.

War and Peace

Studies focusing on the role of gender equality and interstate conflict highlight the relationship between international violence and domestic gender equality (Caprioli, 2000, 2003; Caprioli and Boyer, 2001; Tessler and Warriner, 1997). In general, countries characterized by gender inequality are more likely to be involved in interstate disputes and more likely to rely on violence to settle those disputes.

Monty Marshall and Donna Ramsey (1999) conducted what may be the first quantitative study of feminist international relations theories regarding state behavior. The authors tested the feminist claim that issues of gender are important in predicting the use of force during interstate disputes. They included gender empowerment in their multiple regression, first to test whether gender equality helped predict state use of force, and second as a means of broadening our understanding of democracy within the democratic peace literature by using gender equality as one indicator of the entrenchment of democratic values. Although the authors make no strong causal inferences based on their analysis, they do find a robust relationship between gender empowerment and the willingness of states to use force. The authors further argue that the use of violence institutionalizes discrimination and inhibits further gender equality. Marshall and Ramsey (1999: p. 32) conclude "that gender theory and analysis may be successfully integrated with traditional international relations theory and quantitative research methods".

Adding to the quantitative feminist international relations literature, Caprioli (2000) drew upon the empirical findings of the public opinion surveys discussed above to test the potential impact of domestic gender equality on state behavior internationally. She used logistic regression to test the relationship between several measures of women's social, economic, and political equality and the escalation of violence during militarized interstate disputes. Caprioli concludes that higher levels of domestic gender equality result in less emphasis on military action in settling international disputes.

Caprioli and Boyer (2001) extend Caprioli's earlier work to assess the impact of domestic gender equality on state's international crisis behavior. The authors provide an empirically based descriptive analysis of the behavior of states with female leaders as primary decision makers during times of

Certain sections of this article are reprinted with publisher's permission from Hudson, Valerie, Charli Carpenter, Mary Caprioli, 2010. Gender and Global Security. In: Robert A. Denemark (Ed.), The International Studies Encyclopedia. Blackwell, New York.

international crises. They then use logistic regression to test the relationship between domestic gender equality and the level of violence exhibited during international crises, concluding that the severity of violence in a crisis does decrease as domestic gender equality increases.

In a later study, Caprioli (2003) further tested the relationship between domestic gender equality and state behavior during militarized interstate disputes. In this piece, she included an analysis relating gendered structural inequality to domestic norms of violence. Using logistic regression to assess the role of domestic gender equality in predicting the likelihood of a state using force first during interstate disputes permits a more rigorous test of the author's earlier work by isolating the effects of reciprocated violence. Caprioli concludes that higher levels of gender equality lower the level of state aggression during interstate disputes. In other words, states with higher levels of gender inequality are more likely to use force first in interstate disputes.

Patrick Regan and Aida Paskeviciute (2003) extended the analysis of gender equality and state use of force internationally beyond the state level by focusing on whether the gender distribution of political power at the societal level influences the willingness of the ruling elite to engage in interstate disputes. The authors conclude that women's access to the political arena helps predict the likelihood of a state engaging in interstate disputes and war. They also explore the extent to which fertility rates and rates of women's employment are associated with the use of force by a state. Provocatively, and in contrast to the democratic peace theory, they argue that pairs of nations with low fertility rates (representing a higher status for women in society) do not fight each other (see also Fukuyama's gendered alternative explanation of the democratic peace thesis (1998)). The authors offer a policy prescription suggesting that support for family planning facilities can facilitate more peaceful interstate relations.

Caprioli and Peter Trumbore, using established cross-national data sets such as the Correlates of War find that states characterized by norms of gender and ethnic inequality as well as human rights abuses are more likely to become involved in militarized interstate disputes and in violent interstate disputes, to be the aggressors during international disputes, and to rely on force when involved in an international dispute (Caprioli and Trumbore, 2003a,b, 2006). David Sobek and coauthors confirm Caprioli and Trumbore's findings that domestic norms centered on equality and respect for human rights reduce international conflict (Sobek et al., 2006).

Hudson and coauthors examine the links between the security of women and the security of states, using data from the WomanStats Project, the Global Peace Index, and other data sources. Hudson and Den Boer (2004) research the extent to which women are missing from Asian populations, finding that in some of the most populous Asian nations, including China and India, which accounts for approximately 40% of world population, that birth and childhood sex ratios are becoming more abnormal and masculinized over time. They ask what effects the creation of a subgroup of the young adult male population who will not be able to become heads of household will have on national security. They find that 12–15% of the young men in this age-group in China and India will be 'bare branches', the Chinese term given to young men who became in effect surplus during historical time periods of prevalent female infanticide. Probing historical and aggregate empirical work, they find that societal instability, primarily in the form of violent crime rates, increase significantly as a result, and that the strategies used by governments to mitigate this growing instability may have regional security ramifications.

Hudson et al. (2008/2009) investigate whether there is a relationship between the level of violence against women in society, and state levels of peacefulness and compliance with international norms. They find a strong relationship, and in multivariate analysis this relationship is more predictive of state peacefulness and norm compliance than levels of democracy, levels of wealth, or presence of Islamic civilization. Furthermore, Hudson et al. (2012b) find a strong relationship between inequities in family law within a society and its level of violence against women. Putting these two articles together, it can be argued that variables related to the status of women may be much more important in understanding high politics than Security Studies has heretofore understood.

Hudson et al. (2012a) broaden their focus to examine how three particular aspects of female subordination – lack of physical security, lack of equity in family law, and lack of parity in collective decision making – undermine not only the security of women, but also create authoritarian, unstable, and bellicose states. Hudson et al. (forthcoming) are also able to trace how systematic female subordination encourages the growth of clan-based societies that undermine not only democratic rule, but also national economic growth and levels of national stability.

In sum, this body of work demonstrates that the promotion of gender equality goes far beyond the issue of social justice and has important consequences for national and international security. Using conventional methodologies, these authors are able to demonstrate a real linkage between the security of women and the security of states. Indeed, this linkage may be stronger than that posited for the democratic peace, or the capitalist peace. It may be more important for national and international security what family law looks like in a given state than how highly it is rated in the Freedom House index.

Female Leadership and Use of Force

Alice Eagly and her coauthors have found important differences in leadership style between men and women (Eagly et al., 2003). Performing a meta-analysis of 45 studies of male/female leadership in industrialized nations, they contrast three styles of leadership: transformation, transactional, and laissez-faire. Using the multifactorial leadership questionnaire studies, they associate transformational leadership with instilling respect, purpose, optimism, creativity in subordinates, with an emphasis on mentoring. Transactional leadership is a style that emphasizes interaction based on appeals to the subordinate's self-interest. Laissez-faire style was associated with a lack of involvement on the part of the leader, or a failure to take responsibility.

The authors note that the interplay between leadership roles and gender roles may be significant: "The tendency for the demands of the female gender role and leader roles to be contradictory can also foster differing behavior in female and

male leaders." One reason that gender roles have different implications for female and male leaders is thus that inconsistency often exists between the predominantly communal qualities that perceivers associate with women (e.g., friendly, kind, unselfish) and the predominantly agentic qualities that they generally believe are necessary to succeed as a leader (e.g., assertive, masterful, instrumentally competent).

"People's beliefs about leaders are thus more similar to their beliefs about men than women" (Eagly et al., 2003: p. 572). The authors go on to note that there is a backlash against women leaders who behave in a more directly agentic manner; that is, women who display high levels of competence, or exert authority over men, or use a dominant style of communication are disliked and mistrusted (p. 573). As a result, female leaders must 'temper' their leadership "with sufficient displays of female-typical communal behaviors" (p. 573). The authors note that "negative reactions can be lessened when female leaders are careful to also display warmth and lack of self-interest by, for example, expressing agreement, smiling, supporting others, and explicitly stating an interest in helping others reach their goals" (p. 573).

The meta-analysis included studies with people in both the United States (53%) and other industrialized countries (47%). The authors find that women are more likely to adopt a transformational leadership style than men, and that as a result, women's performance as leaders is on average more effective than that of men.

Natalie Florea et al. (2003) empirically tested hypotheses inspired by feminist research regarding differences in negotiating styles between men and women, using data from a large teaching simulation, GlobalEd, conducted by their university involving students from junior high to college levels. The authors found that gender affected negotiating style based on evidence indicating that all-female groups behaved differently from all-male groups and that mixed gendered groups behaved differently from both single sex groups. Women tended to negotiate by appealing to higher principles such as justice or the consequences on participants (see also Gilligan, 1982).

This research has recently been extended in Boyer et al. (2009). Their simulation allows for the formation of negotiating groups that are all-male, all-female, and mixed gender. While students are aware of the gender composition of their own group, they are blind to the gender composition of the groups with which they are negotiating. There is also a 'mediator', called the SimCon, whose gender is unknown to the negotiating groups. They find that the addition of women alters the behavior of the group. Message volume is higher when females are involved either as negotiators or as mediators. They also find that for junior high students, the presence of a female SimCon increases collaborative and creative styles of negotiating, but for the high school students, a female mediator increases the prevalence of conflictual and assertive styles. They conclude "gender plays a significant role in social and political interaction" (p. 45).

Rose McDermott and Jonathan Cowden examine sex differences in aggression with the context of a simulated crisis game (McDermott and Cowden, 2002). In these experiments with college students, all-female pairs proved significantly less likely than all-male pairs to spend money on weapons procurement or to go to war in the face of a crisis. In further research, McDermott and her coauthors find that in simulation, males are more likely to display overconfidence prior to gaming, and are more likely to use unprovoked violence as a tactic (Johnson et al., 2006). King et al. (1991) had undergraduate students engage in prisoners' dilemma games played over computer. Some students were told the sex of their opponents, while others were not told. The researchers coded the strategies used as being competitive, cooperative, or tit for tat. When their opponents used competitive strategies, students who did not know the sex of their opponent were three times more likely to assume their opponents were male. There is also some evidence from simulation studies that when negotiators take place in the presence of male onlookers, negotiations become more contentious, with outcomes more zero-sum in nature than if negotiators are watched by females (Pruitt et al., 1986). Conversely, this same study finds that when negotiators are negotiating on behalf of women (who may or may not be present), the negotiations are more protracted and difficult than when the negotiators' constituents are male. These types of simulations, despite their constraints, permit the inclusion of sex-based psychological variables in theories concerning the micro processes by which gender differences might affect resulting state security processes and outcomes.

National Stability and Governance

Caprioli (2005) extends her aforementioned findings relating gender equality to interstate behavior to internal or domestic-level conflict. This research tests the implications of feminist theories by providing an analysis of structural violence and the role of gender inequality and discrimination in nationalist uprisings to assess this variable's potential role in predicting intrastate violence. Caprioli uses logistic regression to examine the impact of gender inequality on the likelihood of intrastate conflict and concludes that domestic gender equality reduces the occurrence of intrastate violence. These findings were replicated by Erik Melander (2005). In other words, states characterized by gender inequality are more likely to experience intrastate conflict, confirming the basic link between gender inequality and intrastate conflict.

A considerable amount of case study research also suggests that gender discourses and identities also become a means, during civil conflicts, to create and maintain ethnic, sectarian, or other in-group/out-group identities (Yuval-Davis, 1997; Elshtain, 1987). Because of the role women come to play in such conflicts as symbols, targets, and packages which can be used to send messages between men of contending groups, gender norm policing within in-groups tends to become heightened during periods of conflict. Implications for those concerned with the dampening of civil or ethnic conflict are to avoid policies that reinforce disparate treatment of women by 'their' men within a country context and to promote the opportunities for women to participate and organize collectively on the basis of a shared identity as women (Handrahan, 2004).

Many international institutions nominally include a commitment to the development of democracy worldwide – a sensible thing to do considering the evidence that states with more democratic institutions are less likely to be involved in conflict with other democratic nations (Maoz and Russett,

1993; Ray, 1995). This project cannot be effective if the gender dimensions of democratic state-building are overlooked. Political variables at the state level have been related to the situation of women, most specifically levels of corruption. For example, in a study of 80 countries, a negative correlation between indices of corruption and indices of women's social and economic rights was found (Kaufmann, 1998). Because decreases in political corruption increase investment and growth, gender equity thus exerts additional influence on economic growth (World Bank, 2001). According to an Inter-Parliamentary Union survey of 187 women holding public office in 65 countries (2000), women's presence in politics increases the amount of attention given to social welfare, legal protection, and transparency in government and business, and 80% of respondents said that women's participation restores trust in government. An analysis by Swers concerning the United States concurs in its general conclusions (Swers, 2002).

Furthermore, there is a strong and statistically significant association between high levels of gender inequality and authoritarianism (Betzig, 1986). Betzig finds that polygyny, in particular, is highly predictive of authoritarian government. This is so because polygyny creates an underclass of less-privileged young males who will never become heads of households due to polygyny-induced scarcity of women. Along the same lines, in an empirical analysis of 157 countries, M. Steven Fish (2002) disconfirms the notion that Islamic societies per se are disproportionately involved in conflict or disproportionately suffer from authoritarian rule. Rather, Fish uncovers two indicators that better explain the variance of these variables in the Islamic world: sex ratio and the literacy gap between males and females. Fish finds that models incorporating these two variables are significantly correlated to authoritarianism in Islamic countries. He hypothesizes that the oppression of females – one of the earliest social acts observed by all in the society – provides the template for other types of oppression, including authoritarianism, in Islamic nation-states.

National Economic Development and Women

A substantial literature links the treatment of women to important state-level variables. Scholarly attention to the link between women and the state arguably began in the field of development. As early as 1970, Ester Boserup argued that omission of gender aspects of development led to project failure. Since her pioneering work, we have seen fruitful waves of successive research in the paradigms of Women in Development, Women and Development, and Gender and Development (Rathgeber, 1990; Chen, 1992; Jacobson et al., 1992; Sen, 1989; Chowdry and Nair, 2002), and the establishment of strong cross-national linkages between gender variables and economic variables.

Examples of the impact of women and women's labor on development are plentiful. According to a recent study by the World Economic Forum, the lower the gender gap within a country, the higher its global competitiveness ranking, and the higher its level of gross domestic product (GDP) per capita (2007: p. 21). The World Bank notes that in nearly all countries, women work longer hours than men, given their double day of productive and reproductive activities, and that women dominate nonmarket activities in all countries (World Bank, 2001). Studies show that an increase in women's income increases the share of household money spent on education, health, and nutrition, while simultaneously decreasing the share of household income spent on alcohol and cigarettes (Hoddinott and Haddad, 1995). A series of striking studies show that the effect of female income on child survival is nearly 20 times larger than that of male income (Thomas, 1990; Thomas et al., 1997). Micro-credit loans to women, pioneered by Nobel Peace Prize winner Muhammad Yunus, provide greater returns to families than micro-credit loans to men (Yunus and Jolis, 2003). It has also been shown that the proportion of the workforce that is female bears a statistically significant relationship to the level of national economic growth (Klasen, 1999) and performance (King and Mason, 2001).

As a result of these research results, regional and global development planners now routinely address the role of women in successful development. For example, the UN Millennium Goals include the goal of empowering women, and occasioned 'Women Watch 2000' (later renamed The World's Women), an effort to more closely monitor the status of women on a cross-national basis to formulate nontraditional indicators of development (UN, 2005). The path-breaking Arab Human Development Report of 2002 identified the generally low status of women in Arab societies to be one of the four major variables retarding growth and advancement therein. This argument was elaborated in the report of 2005, which argues, "the rise of women is in fact a prerequisite for an Arab renaissance, inseparably and causally linked to the fate of the Arab world" (AHDR, 2005: p. 24).

As development became more integrated with a gender perspective, other state-level phenomena also began to be seen through a gender lens, with important results. Analysis of the effects of women's education was a natural next step. For example, the World Bank has concluded that low investment in female education reduces a country's overall output. One study found that if South Asia, Sub-Saharan Africa and the Middle East, and North Africa had invested earlier in closing gender gaps in education, their income per capita would have increased by 0.5–0.9 from 1960 to 1992 (World Bank, 2001). A study of 90 nation-states concluded that a 1% increase in female to male primary enrollment rates increases GDP growth by 0.012% (Eteve-Volart, 2000). In addition, the more education a mother has, the lower her children's mortality rates, even after controlling for household income and socioeconomic status (Jejeebhoy, 1995; Schultz, 1993). A study from the Philippines concluded that a mother's education contributed more to her children's health status than household income (Barrera, 1990), and another cross-national study of 63 nation-states determined that women's education was the single most important factor in levels of malnutrition over a 25-year period (Smith and Haddad, 2000).

The world is now beginning to recognize that the status of women often substantially influences important aspects of the states in which they live (Hunt, 2007). Many now readily acknowledge the empirically established relationship between the situation of women, and state welfare and even state prosperity. An emerging empirical literature is able to

demonstrate the linkage between the security of women and the security of the states in which they live. We are fast approaching the day when it will be impossible to credibly comment on national and international security affairs without a knowledge of the situation and status of women.

This article is a revision of the previous edition article by A. Siewierska, volume 24, pp. 16552–16555, © 2001, Elsevier Ltd.

Abstract

The way constituents are ordered in a linguistic expression is determined by general principles and language-specific rules. This article is mostly concerned with general ordering principles and the three main linguistic categories that are relevant for constituent order research: formal, functional, and semantic categories. The general principles appear to be motivated by cognitive considerations, which are deemed to facilitate language processing and which can all be regarded as manifestations of iconicity: nonarbitrary relations between the form and the content of a linguistic expression. Three major iconic ordering principles are the principles of Domain Integrity, Scope, and Head Proximity.

Introduction

The way words or groups of words are ordered in any particular language is always meaningful, so that when a language allows for alternative ordering patterns, each variant should be regarded as communicatively significant. For instance, the English sentence 'The woman called the doctor' does not mean the same as 'The doctor called the woman.' To give another example, in Spanish one can find both *mi amigo viejo* (lit. 'my friend old') and *mi viejo amigo* (lit. 'my old friend'), but *mi amigo viejo* (with the noun preceding the adjective) means 'my elderly friend' ('my friend who is old'), whereas *mi viejo amigo* (with the adjective preceding the noun) expresses emotional content: 'my old/dear/longtime friend.' Even in so-called 'free word order' languages, it is not the case that each possible order is fully grammatical or acceptable under all circumstances (Dik, 1997, pp. 18, 394; Heine and König, 2010, p. 87).

Speech is inherently linear as we can only pronounce one word at a time, but from a crosslinguistic perspective it appears that some ordering patterns are selected on a language-specific basis to structure discourse, whereas in other cases the linear organization of speech appears to be motivated or constrained by general cognitive considerations (e.g., for communicative purposes or to facilitate language processing), which would explain why we find certain ordering tendencies in languages across the globe. Thus, whether the object argument precedes the verb (as in Turkish) or follows it (as in English) in the unmarked declarative sentence of a language is probably not due to any general ordering preference, as in this particular case there is no obvious reason why one order should be preferred over the other in human communication. Furthermore, Object–Verb order and Verb–Object order are more or less evenly distributed in languages across the globe (which might also be due to chance, of course).

On the other hand, there are several reasons why the subject argument commonly precedes the object argument in the languages of the world: 'Subject before Object' mirrors the fact that language users prefer to process GIVEN before NEW information, i.e., WHAT IS BEING TALKED ABOUT (Topic or Theme) before WHAT IS BEING SAID ABOUT IT (Focus or Rheme). The insight that constituents which help the hearer to interpret the rest of the clause normally appear at the beginning is commonly attributed to the Prague School of Linguistics in the first half of the twentieth century, which divided the communicative structure of the sentence into a thematic and a rhematic part, but statements to the same effect can already be found in Weil (1844, p. 19).

As may be clear from these introductory paragraphs, the current article discusses word order from a functional–typological perspective, which means that, in addition to formal aspects, due attention is also paid to semantic and functional (pragmatic) factors.

Before we continue, we should mention two issues. First of all, since word order studies are concerned with the order of INDIVIDUAL WORDS as well as GROUPS OF WORDS that function as a single unit in a larger linguistic expression, it would be more appropriate to use the term 'constituent.' For this reason 'constituent order' will be the preferred term in the remaining part of this article.

Secondly, the current contribution is restricted to constituents that are properly contained in a linguistic unit or domain (section 'General Tendencies in Constituent Ordering') like a clause or a noun phrase (NP). Not all studies on constituent order indicate whether the constituents they discuss are actually an integral part of a clause or an NP (rather than e.g., an afterthought or an apposition), but failing to make this distinction gives an unreliable picture of the true ordering possibilities within a phrase or clause. For example, a complete clause often contains one or more extraclausal constituents, as in (with extraclausal constituents in italics):

1. *Well*, what do you think, *Michelle*?
2. *By the way*, I shouldn't have said that.

In the case of phrases, a distinction is often made between 'tight' and 'loose constituency.' An extreme case of 'loose constituency' is attested in Kalkatungu (Australia). In this language "there are in fact no NPs, but [...] where an argument is represented by more than one word we have nominals in parallel or in apposition. [...] Each word is a constituent of the clause [...]" (Blake, 1983, p. 145).

In other languages only postposed elements are regarded as loosely connected or 'appositional' elements. For example, in the Caucasian language Georgian a postposed modifier behaves more like a separate NP, or apposition, in that it

inflects for the full set of cases and numbers (Testelec, 1997, p. 652). This is illustrated in (3b).

Georgian

3 a. *am* *or-Ø* *lamaz-Ø* *kal-s*
that:OBL two-DT nice-DT woman-DAT
'to those two nice women'

b. *kal-eb-s* *lamaz-eb-s*
woman-PL-DAT nice-PL-DAT
'to the nice women'

Thus, constituents such as 'well' and 'Michelle' in (1), 'by the way' in (2), and Georgian *lamaz-eb-s* (nice-PL-DAT) in (3b) will not be taken into account.

In addition to offering a brief outline of main developments in the history of constituent order research (section 'Traditional Constituent Order Typology'), this article discusses some problems and recent developments in this area, in particular the way in which constituents are identified and compared across languages. Since certain semantic categories (like basic color terms) or form-based categories (word classes such as adjectives or prepositions) are not attested in all languages, and since the same constituent may have different discourse functions (and conversely, since the same function can be fulfilled by constituents belonging to different form classes), we need semantic, formal as well as functional categories to account for constituent order phenomena in all the world's languages (section 'Form and Function in Constituent Order'). Constituent order studies have been mainly concerned with the relative order of (1) subject, object, and verb in the clause and (2) certain adnominal modifiers (typically adjectives, numerals, and demonstratives). The present survey is somewhat biased toward the NP, as constituent order in this phrase has been investigated in considerable detail in some large crosslinguistic studies (Hawkins, 1983; Dryer, 1992; Rijkhoff, 2004; Cinque, 2005).

Investigating Constituent Order across Languages: Some General Issues

Constituent order is not equally relevant for all languages. The study of constituent order presupposes that there are constituents that appear in certain linear patterns, but what is expressed as a free constituent in one language can be expressed as a morphologically bound form in another languages. This is particularly true in the case of incorporating or polysynthetic languages, as illustrated by this example from the Australian language Tiwi (Blake, 2006, p. 591):

Tiwi

4. *Pitiwuliyondjirrurlimpirrani*
Pi-ti-wuliyondji-rrurlimpirr-ani.
3 PL-3 Sg.fem-dead.wallaby-carry.on.shoulders-PT.HABIT
'They would carry the dead wallaby on their shoulders.'

It is also possible to find polysynthesis in phrases. Since in Nivkh (Siberia, Russia) "dependent-head synthesis is obligatory with nominal heads" (Mattissen, 2002, p. 152), demonstratives, numerals, and adjectives all appear as bound forms, as in (Mattissen, 2002, p. 156):

Nivkh

5. *t'-vila-Gan*
2Sg-big-dog
'your big dog'

A crosslinguistic comparison of constituent order can also be affected by the fact that languages do not necessarily share the same set of categories. For example, the Amazonian language Pirahã is deemed to have no color terms and adnominal demonstratives are absent in Hixkaryana (another Amazonian language from Brazil). Furthermore it appears that true numerals are not attested in all languages and that in some languages the expression for a cardinal number must be accompanied by a gesture; in fact in some languages (e.g., the Papuan language Kobon) the gesture alone can suffice.

Then there is the problem that the translational equivalents of some form or construction can be too varied for crosslinguistic comparison (section 'The Employment of Semantic Criteria in Constituent Order Research'). For example, a distinct class of true adjectives is lacking in many of the world's languages, in particular outside Europe. Such languages typically employ phrasal or clausal structures headed by a stative verb ('be.pretty$_V$,' 'be.silent$_V$') or an abstract noun ('prettiness$_N$,' 'silence$_N$') to express adjectival notions in the NP, as shown in these examples from Kiribati (Kiribati, Micronesia) and Makwe (Palme, Mozambique).

Kiribati (Ross, 1998, p. 90)

6 a. *E* *tikiraoi.*
3Sg.S be.pretty
'She/He is pretty.'

b. *te* uee *ae* *e* *tikiraoi*

'a pretty flower'

Makwe (Devos, 2008, p. 136)

7. *muú-nu* *w-á=ki-búúli*
NC1-person PP1-GEN=NC7-silence
'a silent person' (lit. 'person of silence')

Similar things can be said about the various ways numeral modifiers are expressed across the globe, as in quite a few languages cardinal numerals are regarded as morphological verbs or nouns. Notice also that many African languages (e.g., Igbo, Hausa) only have a minor, closed class of nonderived adjectives.

Another reason why certain constituent orders may not be found in all the world's languages has to do with the fact that speakers of a language fail to realize certain ordering sequences in normal discourse, even though these patterns are deemed grammatically possible. According to Lyle Campbell (personal communication), there would be nothing ungrammatical about an NP containing a demonstrative, a numeral, and an

adjective in Pipil (El Salvador), in which case the order would be [dem num A N], but apparently this never happens in actual discourse. Some languages have structural constraints that prevent certain constituents from appearing simultaneously in the same phrase or clause. Thus, a lexical NP can accommodate only one modifier in Yimas (New Guinea). Any other modifying material must take an agreement suffix and occur as an appositional phrase (Foley, 1991, pp. 184–188).

When such factors (polysynthesis, apposition, co-occurrence restrictions, etc.) are taken into consideration, quite a few languages are excluded from a crosslinguistic investigation of constituent order. For example, because of the issues mentioned above (but also because of e.g., 'dependency reversal'; cf Malchukov, 2000), the relative order of demonstrative, numeral, adjective, and head noun could only be established for less than half of the languages in a representative sample of the world's languages (Rijkhoff, 2004, p. 327–329).

Traditional Constituent Order Typology

Especially since Greenberg (1963), constituent order typology has mainly been concerned with two issues:

1. classification of languages on the basis of the relative order of the verb (V) and its arguments subject S and object O in a transitive clause (which gives six logically possible patterns: SOV, SVO, VSO, OSV, OVS, VOS – see the section Classification of Languages in Terms of 'Basic Constituent Order');
2. establishing correlations between ordering patterns (e.g., between the order of verb and object on the one hand and between noun and relative clause on the other; see below on Constituent Order Correlations).

A further section is concerned with some problems in Traditional Constituent Order Typology.

Classification of Languages in Terms of 'Basic Constituent Order'

In traditional constituent order typology, it was initially assumed that V, S, and O are labels for categories which are relevant for all languages and that each language uses one of the six logically possible ordering patters of V, S, and O as the 'basic word order.' Based on a large-scale investigation, Tomlin (1986) proposed that some 45% of the world's languages have SOV as the basic order and that in 42% SVO and in 9% VSO is the basic order (for discussion, see Dryer, 2005; Song, 2012). Only a very small percentage of the world's languages have Object before Subject as the basic order: 3% of the languages are deemed to employ VOS order and 1% OVS order. There were no OSV languages in Tomlin's sample, but the Amazonian language Nadëb, for instance, has since been claimed to have OSV as the unmarked order (Weir, 1994, p. 292).

In spite of these results, the classification of languages in terms of the basic order of V, S, and O can be problematic, especially from a crosslinguistic perspective (Song, 2012, pp. 14–15). For example, the notion 'subject' is deemed irrelevant for 'topic prominent' languages, languages without an active–passive opposition and languages with an ergative–absolutive alignment system (Dik, 1997, pp. 247–289). It has also been claimed that there are languages without a distinct class of verbs (Rijkhoff and van Lier, 2013).

Furthermore, 'basic order' is commonly defined as "the order that occurs in stylistically neutral, independent, indicative clauses with full noun phrase (NP) participants, where the subject is definite, agentive and human, the object is a definite semantic patient, and the verb represents an action, not a state or an event" (Siewierska, 1988, p. 8). However, clauses in which both arguments of a transitive verb are expressed as definite lexical phrases (as in '*The dog chased the cat*') are very infrequent in natural language, especially in the spoken variety (Siewierska, 1988, pp. 8–14).

Constituent Order Correlations

The first serious investigation of correlations between constituent order patterns is undoubtedly Greenberg's (1963) seminal crosslinguistic survey, which led to the formulation of implicational universals. Greenberg classified languages on the basis of the unmarked order of nominal subject (S), verb (V), and nominal object (O), which resulted in three groups: languages with basic order VSO, SVO, or SOV. This is shown in **Table 1**, which is based on Hawkins's (1983) more recent study. Notice that here 'V-1' ('Verb-initial') is used, rather than 'VSO' as in Greenberg's original publication (A = adjective, G = genitive/possessor phrase).

Table 1 shows, among other things, that most SOV languages have both the adjective and the genitive preceding the noun (type 11), whereas most V-1 and SVO languages have these modifiers following the noun (types 1 and 5).

Greenberg (1963) also formulated 45 'universals of grammar with particular reference to the order of meaningful elements'; for example:

Universal 16. In languages with dominant order VSO, an inflected auxiliary always precedes the main verb. In languages with dominant order SOV, an inflected auxiliary always follows the main verb.

Universal 17. With overwhelmingly more than chance frequency, languages with dominant order VSO have the adjective after the noun.

Universal 18. When the descriptive adjective precedes the noun, the demonstrative and the numeral, with overwhelmingly more than chance frequency, do likewise.

In the same article Greenberg (1963, pp. 96–104) offered tentative explanations for some of his findings, suggesting that several ordering sequences could be accounted for in terms of two competing motivations: Dominance and Harmony. For example, a language that has the head-initial pairs VS–VO–NA–NG (where V and N are the head of the

Table 1 Classification of languages (based on Hawkins, 1983; '—' signals that both A and G precede or follow the head noun N)

1. V-1 & N—	38	5. SVO & N—	56	9. SOV & N—	21
2. V-1 & ANG	13	6. SVO & ANG	17	10. SOV & ANG	0
3. V-1 & —N	2	7. SVO & —N	19	11. SOV & —N	98
4. V-1 & GNA	0	8. SVO & GNA	17	12. SOV & GNA	55
	53 lgs.		109 lgs.		174 lgs.

clause and the NP, respectively) is 'harmonic' and the same goes for languages with the head-final pairs SV–OV–AN–GN. The notion 'dominance' can be exemplified with Hawkins's Universal VI (see (9)), as summarized in Table 2 (Rel = relative clause). Since GN order occurs with both NRel and RelN order, GN is regarded as the dominant order (Tigre, mainly spoken in Eritrea, seems to be an exception with RelN and NG order). Greenberg added, however, that his theory was far from complete and emphasized that disharmonic and nondominant (or: 'recessive') patterns should not be ignored.

Subsequently Lehmann (1973) and Vennemann (1975) offered more radical accounts for Greenberg's findings, essentially reducing his three-way typology (VSO, SVO, SOV) to two 'word order types' (see Song, 2012, pp. 17–21, 29–54) for detailed discussion of two-way ordering typologies). Lehmann's *Fundamental Principle of Placement* suggested it is possible to predict certain ordering pairs (such as the order of adjective and noun), if one knows that the language has OV or VO as the basic order. According to Vennemann's *Principle of Natural Serialization* constituents are either Operators or Operands, which tend to be serialized either with Operator before Operand or with Operand before Operator. Examples of Operators would be 'object' and 'adverbial,' both of which have 'verb' as their Operand. Even though there are many languages with ordering patterns that deviate from Lehmann's or Vennemann's ideal types, such languages were largely ignored as they were deemed to be in the process of changing from one type to another due to internal development or contact.

Greenberg's original tripartite typology (Table 1) was restored in Hawkins's (1983) monograph on constituent order universals. Using a sample containing over 300 languages, Hawkins formulated some new, often exceptionless universals (but see Dryer (1992) and Rijkhoff (2004, p. 227) for counterexamples). For instance (Hawkins, 1983, pp. 64, 83):

8. If a language has OV order, then if the adjective precedes the noun, the genitive precedes the noun; i.e., OV ⊃ (AN ⊃ GN).
9. If a language has noun before genitive, then it has noun before relative clause; i.e., NG ⊃ NRel (equivalently: RelN ⊃ GN).

He then demonstrated that various implicational universals could be collapsed into statistical implications with a preposition or postposition as ultimate antecedent (Hawkins, 1983, pp. 75, 83):

10. Prepositional Noun Modifier Hierarchy:
    Prep ⊃ ((NDem ∪ NNum ⊃ NA) & (NA ⊃ NG) & (NG ⊃ NRel))

Table 2 Schematic representation of Universal VI

	NG	*GN*
NRe1	+	+
Re1N	–	+

(cf. Hawkins, 1983, p. 83).

11. Postpositional Noun Modifier Hierarchy:
    Postp ⊃ ((AN ∪ RelN ⊃ DemN & NumN) & (DemN ∪ NumN ⊃ GN))

He also attempted to account in a more principled way for the many languages with ordering patterns that do not quite fit the 'ideal' two-way classification, which had been the focus of Lehmann's and Vennemann's proposals. For example, the *Heaviness Serialization Principle* (Hawkins, 1983, pp. 90–91) deals with the fact that many languages have adnominal modifiers on both sides of the head noun (cf. also the *Mobility Principle* – Hawkins, 1983, pp. 93–97).

Almost a decade later Dryer (1992) used an even bigger sample (625 languages) in an attempt to investigate which constituent order pairs actually correlate with the order of object and verb (OV/VO), because assertions about such correlations had never been substantiated by systematic research (but cf Perkins, 2001, p. 432). Dryer concluded there are indeed several constituent order pairs that more or less correlate with the OV/VO distinction (Table 3), among them the pair HEAD NOUN–POSSESSOR NP (NG/GN) and the pair HEAD NOUN–RELATIVE CLAUSE (NRel/RelN). However, he did not find evidence for a correlation between OV/VO order and, for instance, the order of noun and adjective (AN/NA) or the order of noun and demonstrative (demN/Ndem).

Thus, we tend to find NG and NRel order in VO languages and GN and RelN order in OV languages. To account for the correlation pairs, Dryer proposed the *Branching Direction Theory*, according to which there is tendency for phrasal categories (such as G and Rel) to either precede or follow a member of a nonphrasal category (such as N, A, and other 'verb patterners'). The theory makes no ordering predictions about nonbranching categories like demonstratives or numerals. However, the theory failed to account for some correlation pairs, such as the order of verb and manner adverb (both of which are nonphrasal). Another problem of the *Branching Direction Theory* concerns the categories that are used to make the crosslinguistic comparison (see Rijkhoff (2004, pp. 278–291; Rijkhoff, 2009) and Song (2012, pp. 29–54 for discussion). This is discussed in sections 'The Employment of Semantic Criteria in Constituent Order Research' and 'Categorial Confusion: Mixing 'Semantic' and Formal Categories.'

Some Problems in Traditional Constituent Order Typology

From a crosslinguistic or typological perspective, the notion 'basic constituent order' is problematic for various reasons,

Table 3 Some of Dryer's correlation pairs

Verb patterners	*Object patterners*	*Example*
Verb	Manner adverb	*Ran + slowly*
Adposition	Noun phrase [NP]	*on + the table*
Copula verb	Predicate	*is + a teacher*
'want'	Verb phrase [VP]	*wants + to see Mary*
Noun [N]	Genitive [G]	*father + of John*
Noun [N]	relative clause [Rel]	*movies + that we saw*
Adjective [A]	Standard of comparison	*taller + than Bob*

Dryer, 1992, p. 108; see also Dryer, 2009.

casting some doubt on the assumption that all languages have a basic order. Here we will focus on two problems: (i) the establishment of a basic constituent order (section The Notion 'Basic Constituent Order') and (ii) the employment of semantic categories to identify constituents for comparative (i.e., crosslinguistic) syntactic purposes (section 'The Employment of Semantic Criteria in Constituent Order Research'). The section 'Categorial Confusion: Mixing 'Semantic' and Formal Categories' deals with the problem of categorial confusion and 'The Relevance Of Meaning- And Form-Based Categories For Constituent Order Research' shows that both meaning-based and form-based categories are relevant in the area of constituent order research, provided they are kept separate from each other.

The Notion 'Basic Constituent Order'

Even if it would always be possible to find for each language a representative number of stylistically neutral (active, positive), independent, indicative clauses that contain a transitive verb and lexical subject and object arguments (section 'Investigating Constituent Order across Languages: Some General Issues'), there would still be quite a few languages that, statistically speaking, display no clear preference for just one of the six possible orderings of V, S, and O. To give some examples: in Dutch, where the finite (main or auxiliary/Aux) verb normally appears after the subject in the main clause (SV_{finite} …), the basic order would be SVO in the absence of an auxiliary verb (*De kat ving the vogel* 'The cat caught the bird'), but SAuxOV if the clause contains a finite auxiliary verb, as in: *De kat heeft*$_{Aux}$ *de vogel gevangen*$_{V}$ (lit. 'The cat has the bird caught') 'The cat has caught the bird.' Notice also that in subordinate clauses the whole verbal cluster appears after S and O (SOAuxV or SOVAux), as in *Ik hoorde dat de kat de vogel heeft*$_{Aux}$ *gevangen*$_{V}$/ *gevangen*$_{V}$ *heeft*$_{Aux}$ (lit. 'I heard that the cat the bird has caught/caught has').

To give another example, Ket (a language isolate spoken in Siberia) is typically classified as having two 'basic' orders (SVO/SOV). Furthermore, since this language makes considerable use of incorporation, many transitive verbs appear without lexical subject or object arguments. Constituent order is also claimed to be remarkably free in Yimas, "even in comparison to the relative freedom exhibited by other Papuan languages. Within the clause, there is no set word order pattern at all (in fact, the majority of clauses consist of just a verb, so word order is not much of a question in these cases anyway). […] Word order in Yimas is so free that NPs need not even form a constituent" (Foley, 1991, p. 4).

These remarks also highlight another problem touched upon earlier: that it is rather unusual to find a transitive verb with two full (i.e., lexical) subject and object arguments where the subject is definite, agentive, and human, the object is a definite semantic patient (Siewierska, 1988, p. 8), particularly in normal spoken discourse. As was already mentioned in the section 'Investigating Constituent Order across Languages: Some General Issues,' in polysynthetic languages (but also in other languages) the arguments of a transitive verb are often not expressed as free constituents, but by clitics or affixes, if at all. These problems could indicate that in quite a few languages basic constituent order has been established on the basis of an elicitation procedure, i.e., at the explicit request of the linguistic field worker who provides the native speaker informant with a constructed example, which is, of course, far from ideal.

The Employment of Semantic Criteria in Constituent Order Research

In a crosslinguistic investigation of constituent order patterns, it is important that the constituents involved are sufficiently similar to be identified and compared across languages (Song, 2012, pp. 10–15). Due the enormous degree of morphological and syntactic diversity that is attested in the world's languages, form-based definitions of constituents have generally been avoided in constituent order studies. For example, to say that a noun is a word that is inflected for number is quite irrelevant for the many languages across the globe in which number marking is absent.

Because formal categories are on the whole too language specific, typologists have usually followed Greenberg (1963, p. 74), who applied semantic criteria to identify the various kinds of constituents in his crosslinguistic investigation of ordering patterns. Thus, his semantic category Adjective essentially covers all the forms and constructions that translate as an adjective in English, even if a language does not have a dedicated class of adjectives, but instead uses abstract nouns such as 'bigness$_{N}$' (as in certain Chadic and Bantu languages), or stative verbs like 'be.big$_{V}$' (as in e.g., many SE Asian languages) to express adjectival notions.

Two decades after Greenberg's publication, Hawkins (1983, p. 12) also claimed that semantic criteria 'suffice to make the cross-linguistic equation' and when Dryer (1992, p. 120) investigated 'Greenbergian word order correlations,' he also identified 'different categories largely on the basis of semantic criteria' (more on this in the section 'Categorial Confusion: Mixing 'Semantic' and Formal Categories'). Thus, their studies suggested that, by employing semantically defined categories, the same constituent ordering patterns (e.g., the order of adjective and noun) can be investigated in all the world's languages, even when it is clear from the grammatical description of a language that the constituents involved belong to different form classes, whose members can have their own, form-based ordering preferences (see the section 'The Relevance of Meaning and Form-Based Categories for Constituent Order Research' and 'Different Constituents, Same Function'). In other words, whereas formally defined categories are usually too narrow for crosslinguistic research into constituent order, semantically defined categories can be too wide: they may include forms or constructions that are too varied to allow for crosslinguistic comparison of constituent ordering patterns. In fact, this was already acknowledged in Greenberg's (1963) investigation of language universals. In his discussion of comparative constructions (as in English '*Mary is TALLER THAN BILL*'), he found that the semantic category Comparison is expressed rather differently in languages across the globe. As later shown by Stassen (1984), there are at least five major construction types to express the semantic category of Comparison. For example, whereas English uses an adjective followed by the standard introduced by the marker *than* (as in the example above: Adjective/*taller* – Marker/*than* – Standard/*Bill*), Duala (a Bantu language from Cameroon) employs two predicates: one

expressing the adjectival notion (here *kolo* 'big'), the other is a verb meaning 'to exceed' or 'to surpass' (Stassen, 1984, p. 151).

Duala

12. *Nin ndabo e kolo buka nine.*
this house it big exceed that
'This house is bigger than that.'

Even though the 'exceed construction' constitutes the second largest type in Stassen's 110-language sample, Greenberg writes that he could only formulate *Universal 22* if he left this construction out of consideration.

"*Universal 22*. If in comparisons of superiority the only order or one of the alternative orders is standard-marker-adjective, then the language is postpositional. With overwhelmingly more than chance frequency, if the only order is adjective-marker-standard, the language is prepositional" (Greenberg, 1966, p. 111).

> A number of languages are not entered in [Table 8 on the same page – JR] because they utilize a verb with a general meaning 'to surpass.' This is particularly common in Africa (e.g., Yoruba): 'X is large, surpasses Y.' Loritja, an Australian language which has 'X is large, Y is small,' is likewise not entered
>
> Greenberg, 1963, p. 88

Two further problems concerning the employment of so-called semantic (or 'conceptual') criteria in traditional constituent order research are, firstly, that the semantic criteria are not explicitly listed and, secondly, that in some cases constituents are essentially identified and compared on the basis of functional rather than semantic criteria. For this reason, the notion 'semantic' as employed in traditional constituent order research will henceforth appear in single quote marks. Notice also that semantic categories are not always distinguished from conceptual categories (especially in cognitive linguistics), but there are good reasons why the two categories should not be conflated. Thus, the reason why adjectives and relative clauses can sometimes be grouped together is not because they belong to the same semantic category (see section 'The Relevance of Meaning and Form-Based Categories for Constituent Order Research' and **Table 4** on genuine semantic features like '±animate' and categories like 'color'), but rather because members of both formal categories can serve as a qualifying modifier in the NP, specifying a more or less inherent property of an entity, such as its age, weight, or size (section 'Form and Function in Constituent Order').

Table 4 The same function (Qualifying Modifier) expressed by members of different formal categories (Adjective, Prepositional Phrase, Relative Clause)

	Functional category: Qualifying Modifier (in the NP)		
Semantic categories	*Formal Categories Adjective*	*Prep. Phrase*	*Relative Clause*
Size	*a big N*	*a N of enormous size*	*a N that is rather big*
Value/Quality	*an expensive N*	*a N of great value*	*a N that is pretty cheap*
Age	*a young N*	*a N under age 16*	*a N that is much too young*
Color	*a black N*	*a N of blackness*	*a N that is pitch black*

Categorial Confusion: Mixing 'Semantic' and Formal Categories

In spite of the problems concerning the application of 'semantic' criteria in traditional constituent order research (section 'The Employment of Semantic Criteria in Constituent Order Research'), these criteria continue to be used in syntactic typology, including large-scale projects such as *The World Atlas of Language Structures* (Rijkhoff, 2009a). Thus, Dryer essentially treats the translational equivalents of English adjectives in all languages as members of the 'semantic' category Adjective, but admits that "there are many languages in which what I call adjectives are really verbs, and 'adjectives' modifying nouns are really just a kind of relative clause" (Dryer, 1992, p. 196, fn. 12). However, Dryer's correlation pairs also include Relative Clause (Rel) as an independent category (**Table 3**). If relative clauses can belong to two 'semantic' categories (Adjective and Relative Clause), one cannot properly interpret the *Branching Direction Theory* (section 'Constituent Order Correlations'), where adjectives and relative clauses are treated as members of distinct, nonoverlapping formal categories. Relative clauses are branching or phrasal categories and 'object patterners'; adjectives are nonbranching categories and the order of Adjective and Noun does not correlate with the order of Object and Verb. Whereas the correlations pairs in **Table 3** are presumably all 'semantic' categories (Dryer, 1992, p. 120), the two categories referred to in the *Branching Direction Theory* (viz. phrasal/branching and nonphrasal/nonbranching categories) are unambiguously syntactic (i.e., formal) categories. In sum, it remains unclear what happened with the phrasal or branching members of the 'semantic' category Adjective in the *Branching Direction Theory*.

The same confusion between 'semantic' and formal categories is found in Hawkins (1983), where Greenbergian 'semantic' categories (which may contain members of different form classes) are used to identify constituents and compare ordering patterns in many different languages (Hawkins, 1983, pp. 9–12). However, some of the same category labels (Adjective, Genitive, Relative Clause) are also used when constituents are discussed as part of the Heaviness Hierarchy, which is based on formal criteria (Hawkins, 1983, pp. 90–91):

$$\text{Rel} \geq_R \text{Gen} \geq_R \text{A} \geq_R \text{Dem/Num}$$

"where $\geq_R$ means: 'exhibits more or equal rightward positioning relative to the head noun across languages.' That is heavier noun modifiers occur to the right."

One constituent is heavier than another, if one or more of the following factors imposes an ordering between them: (1) length and quantity of morphemes, (2) quantity of words, (3) syntactic depth of branching nodes, and (4 inclusion of dominated constituents. The different degrees of 'heaviness' would explain why relative clauses, which are comparatively 'heavy,' are more likely to appear after the head noun in prepositional languages than adjectives, which are relatively 'light.' In other words, names for 'semantic' categories (A, Rel etc.) are now used as labels for categories defined on

the basis of formal criteria. Here, too, it remains unclear how verbal and nominal expressions of adjectival notions (see examples (6) and (7)) are categorized in terms of heaviness. Presumably the original members of the single semantic category Adjective are now distributed over several formal categories (including at least A and Rel).

We will see in the section 'Form and Function in Constituent Order' that the confusion between 'semantic' and formal categories in constituent order studies is at least partly due to two problems: (1) the 'semantic' criteria used in traditional constituent order research are in fact sometimes functional criteria in that constituents are occasionally identified and compared on the basis of the function they serve in a linguistic expression (e.g., QUALIFYING MODIFIER) and (2) the same function (e.g., QUALIFYING MODIFIER) can be fulfilled by constituents that belong to different form classes (e.g., adjective, prepositional phrase, relative clause), and vice versa, that the same constituent (e.g., relative clause) can have different functions in actual discourse.

The Relevance of Meaning- and Form-Based Categories for Constituent Order Research

Both semantic and formal criteria are needed to account for the way constituents are linearized in a linguistic expression, but it is very important that they are kept separate. For example, the semantic features '±definite' or '±animate' (often in tandem with other meaning-based or pragmatic notions like 'prominence,' 'topicality,' or 'salience') can have various effects on the grammar of a language (Dik, 1997, pp. 34–41), including the way constituents are linearized. Thus, in some languages the animacy hierarchy determines the order of the two object phrases in clauses with a ditransitive verb (Heine and König, 2010). The following examples are from Kinnauri (Nepal). In (13a) both objects (child, maternal aunt) refer to animate entities, in which case the direct object precedes the indirect object. In (13b), however, the order of the objects in determined by animacy: the animate entity (uncle) precedes the inanimate entity (letter) in the unmarked order (Kittilä, 2006, p. 2).

Kinnauri

13. a. *amas anu chan-u ane-pən rano*
mother:ERG she:REFL child-ACC maternal aunt:ACC send
'The mother sent her son to the maternal aunt'

b. *gəs än bapu-pən cithi cemigduk*
1Sg:ERG 1Sg:GEN uncle-ACC letter write:S
'I have to write a letter to my uncle'

Alamblak (Papua New Guinea) provides us with another example of the relevance of semantics for constituent order. In this language, color adjectives must precede the noun, whereas adjectives belonging to other semantic categories can occur on either side of the head, although some (e.g., adjectives denoting a physical property) tend to precede the noun and others (e.g., those denoting 'value') usually follow the noun. To give another example, in Maybrat (Bird's Head Peninsula, New Guinea) the genitive precedes the noun (GN) in the case of inalienable possession, but follows it (NG) in the case of alienable possession.

Formal factors clearly play a role when, for example, constituent order is determined by the way a constituent is formally expressed, which in its turn is connected with the internal complexity of a constituent (see above on 'morphosyntactic weight' or 'heaviness'). Whether a constituent takes the form of a single word (adjective, adverb), a phrase (NP, PP). or a clause (relative clause) can (co-) determine its position in a linguistic expression (see the section 'Domain Integrity'). The role of structural complexity was already captured in 1932 by Behaghel's *Gesetz der wachsenden Glieder* ('law of growing members'), according to which constituents are arranged in their order of relative increasing complexity (cf 'heavy shift' in transformational grammar and the Principle of Increasing Complexity in Dik's Functional Grammar). Compare

14. a. ?I gave *the paintings that my uncle left to me as part of his inheritance* to her.
b. I gave to her *the paintings that my uncle left to me as part of his inheritance*.

The version with the long constituent in clause-final position (14b) is preferred over the one with the short constituent ('to her') at the end (14a). The same holds for heavy constituents in the NP: the short *of*-phrase in (15a) can appear immediately after the head noun, but the preferred position of the longer *of*-phrase is at the end of the NP, as in (15b).

15. a. the painting *of him* that she found
b. the painting that she found of *her grandfather wearing that strange jacket*

In sum, it is necessary to distinguish between meaning-based and form-based categories, as both play their own distinct role in structuring discourse through constituent order. For a more complete and satisfactory account of constituent order, however, the discourse function of a constituent in actual speech also needs to be taken into consideration; this is discussed in the section 'Form and Function in Constituent Order.'

Form and Function in Constituent Order

An important reason why 'semantic' and formal categories have been mixed up in some constituent order studies is that these studies did not distinguish between semantics and pragmatics, i.e., between the coded meaning of a constituent and the discourse function of a constituent in an actual utterance (section 'Categorial confusion: mixing 'semantic' and formal categories'). This means that functional categorization is essentially context dependent (see e.g., the introduction about 'Subject before Object'). Furthermore, not all constituent order studies took into account that there is often no direct correspondence between the form and the function of a constituent. The same constituent (e.g., a relative clause) can have different functions in interpersonal communication (section 'Same Constituent, Different Functions'), and vice versa, constituents belonging to different formal categories (e.g., adjectives and relative clauses) can be used in the same function (section 'Different Constituents, Same Function'). In either

case we see that the discourse function of a constituent in actual speech may put certain constraints on its ordering possibilities.

Functional Modifier Categories

The functional, instrumental approach to categorization can be said to have its roots in the Prague School of Linguistics, which has greatly influenced current functional theories of grammar. Functional categorization is not directly concerned with the formal or semantic properties of a constituent, but rather with the actual job of a linguistic form or construction in the process of verbal communication. Here we will only deal with some FUNCTIONAL MODIFIER CATEGORIES that are relevant for both NPs and clauses (for details, see Rijkhoff, 2008a,c). They are briefly characterized in (16a–e), where they are listed according to scope increase. Thus, a CLASSIFYING MODIFIER such as 'presidential' in 'the presidential election' only has the head constituent ('election') in its scope, whereas a DISCOURSE-REFERENTIAL MODIFIER like a definite or indefinite article has all other constituents of an NP in its scope (see also the section 'Different Constituents, Same Function' on the Scope Principle).

16. Five functional modifier categories in NPs and clauses (with examples of English adnominal modifiers)
    a. CLASSIFYING MODIFIERS further specify what KIND of entity (subcategory) is denoted by the head constituent (as in e.g., 'SOLAR energy,' 'a VIRAL infection,' 'a man OF THE STAGE');
    b. QUALIFYING MODIFIERS specify more or less inherent properties ('qualities') of an entity (e.g., 'a BLUE hat,' 'children UNDER AGE 16,' 'a house THAT WAS RATHER BIG');
    c. QUANTIFYING MODIFIERS specify quantitative properties (quantity, number, cardinality) of an entity (e.g., 'TWO cars,' 'SEVERAL books');
    d. LOCALIZING or ANCHORING MODIFIERS specify locative properties of an entity in spatial, temporal, or cognitive dimension. By 'anchoring' an entity in the world of discourse, the speaker makes the referent identifiable for the hearer (e.g., 'THIS car,' 'the house ON THE CORNER,' 'That's the man WHO STOLE MY BIKE');
    e. DISCOURSE-REFERENTIAL MODIFIERS specify discourse-referential (pragmatic) properties of an entity (e.g., 'THE/A car').

Since there is often no one-to-one correspondence between the form and the function of a constituent, the same constituent can have different functions in actual speech. Thus, an adnominal demonstrative is a LOCALIZING MODIFIER in its deictic function, but a DISCOURSE-REFERENTIAL MODIFIER when it merely marks definiteness (section 'Different Constituents, Same Function'). Similarly, a relative clause is a QUALIFYING MODIFIER when it serves to express a more or less inherent property (example (16b), but a LOCALIZING/ANCHORING MODIFIER when it is used to make the referent of an NP identifiable (as in example (16d)). Conversely, constituents that belong to different formal categories (e.g., adjectives and relative clauses) can be used in the same function (e.g., QUALIFYING MODIFIER – see **Table 4**). The many-to-many correspondence between the form and the function of constituents and its relevance for constituent order is discussed in the sections 'Same Constituent, Different Functions' and 'Different Constituents, Same Function.'

Same Constituent, Different Functions

Membership of formal categories such as Adjective, Relative Clause, or Complement Clause is generally not a very reliable indicator of the discourse function of a constituent in actual speech. For example, the adjective 'civil' is a CLASSIFYING MODIFIER in 'civil rights' (implying e.g., that it cannot be modified by a degree adverb: *very civil rights), whereas 'civil' in 'a civil reply' serves as a QUALIFYING MODIFIER (which means it can be modified by a degree adverb: 'a very civil reply') (Halliday, 2004, pp. 320–322; Bisetto, 2010).

There are many examples of constituents whose actual function in an utterance is marked by constituent order. Berbice Dutch Creole is one of the languages in which the same constituent can be used as a definite article or as an adnominal demonstrative modifier, but as an article it precedes the noun and when it has a deictic (localizing) function it follows the noun. When a numeral appears before the noun in Russian (num N) it expresses cardinality (*dvadcat' knig* ' twenty books'), but when the order is reversed (N num) the numeral has an approximative meaning (*knig dvadcat'* 'approximately twenty books'). In Turkish and many other languages the same constituent can occur as an indefinite article or as the numeral 'one' (in Turkish *bir*). The position of *bir* in the NP is determined by its actual modifier function. Similar things can be said about adnominal possessor phrases or genitives and relative clauses. For example, in the Nepalese language Kham a qualifying relative clause appears immediately before the noun, whereas a localizing relative clause normally precedes the numeral and clusters with other localizing modifiers in the order (see the section 'Functional Modifier Categories'): [dem Rel num Rel N].

Different Constituents, Same Function

The fact that the same function can be fulfilled by constituents that belong to different form classes is seen in **Table 4**, which shows that English adjectives, prepositional phrases, and relative clauses can all be used as a descriptive or QUALIFYING MODIFIER, which specifies a more or less inherent property of an entity.

According to the Scope Principle (section Scope), constituents that belong to the same functional modifier category occupy the same position before or after the head constituent. This was shown to be the case in the Nepalese language Kham (section 'Same Constituent, Different Functions'), where qualifying relative clauses (but not localizing relative clauses) occupy the same position as true adjectives in other languages (cf the ordering patterns in (31)).

When a language has alternative forms of expression for the same function (**Table 4**), the choice is often determined by linguistic genre, pragmatic considerations, or internal complexity (section 'The Relevance of Meaning- and Form-Based Categories for Constituent Order Research'). This can be seen in (18), where the 'heavy' postnominal qualifying

relative clause contains coordinated constituents (both examples from the Internet).

17. *I am looking for a* RATHER BIG$_A$ *house* ….
18. *Indeed there was a house* THAT WAS RATHER BIG AND VERY PRETTY$_{REL}$.

General Tendencies in Constituent Ordering

Globally observed constituent ordering tendencies are generally regarded as manifestations of iconicity: nonarbitrary relations between 'form' and 'content' (Haiman, 1985). Iconicity in grammar concerns any formal manifestation of the (largely unconscious) effort to maintain a close correspondence between, on the one hand, nonlinear, multidimensional MENTAL representations of entities (as well as relations between these entities) and, on the other hand, the way these representations are mapped onto a linear, one-dimensional structure in speech. Constituent order is considered iconic whenever it reflects aspects of the conceptual or semantic content, which typically manifests itself as 'iconicity of distance,' where conceptual or semantic distance matches with spatial distance. Especially among functional linguists, it is widely assumed that there is direct causal connection between iconicity in grammar and increased communicative efficiency.

Under the narrow view of iconicity, the notion refers to the tendency of linguistic expressions to mirror the temporal or logical sequential order of events. This can be seen in (19a–b), where the coordinated clauses in the a-sentence (but not in the b-sentence) reflect the actual order of events.

19. a. They met in Konstanz and married in Amsterdam. (unmarked)
    b. ?They married in Amsterdam and met in Konstanz. (marked)

Another instance of iconicity in the narrow sense is the order of clauses in conditional sentences (e.g., 'If he comes, I'll leave'), where the condition (*protasis*) precedes the consequence (*apodosis*) as the unmarked order in all languages (Universal 14 – Greenberg, 1963, p. 84).

In its broad sense, iconicity also refers to any correspondence between linguistic expressions and "generally accepted perceptions of dominance and salience and/or semantic dependencies" (Siewierska, 2006, p. 646). Defined this way, iconicity accounts for several of the general ordering tendencies mentioned earlier, such as the strong universal preference for Subject arguments to precede Object arguments (subjects tend to be agentive, definite, more salient and higher on the person and animacy hierarchy than objects) and even the tendency to place long and complex constituents after relatively short, less complex constituents. The use of informationally and structurally 'light' constituents correlates with topicality and high identifiability: placing light constituents before heavy constituents would iconically reflect the preferred way of processing information.

Behagel's famous first law (1932, p. 4) already captured the insight that constituent order is often an iconic reflection of the way we perceive or conceptualize entities or relations between entities to facilitate language processing.

20. Behaghel's First Law
    Das oberste Gesetz ist dieses, daß das geistig eng Zusammengehörige auch eng zusammengestellt wird ('The principal law is this: that what belongs together mentally is also placed close together').

It is possible to formulate more precise iconic subprinciples on the basis of Behaghel's first law: (1) the Principle of Domain Integrity (PDI), (2) the Principle of Head Proximity (PHP), and (3) the Principle of Scope (PoS) (Rijkhoff, 2004, 2008b). These principles are briefly discussed below, mostly illustrated with examples involving NP-internal constituents, as the effects of the various principles are better seen at the level of the phrase than in the larger clausal domain.

Domain Integrity

The PDI can be formulated as follows:

21. Constituents prefer to remain within the boundaries of their proper domain; embedded domains (subordinate clauses or phrasal modifiers such as adnominal possessive NPs) prefer to be in the periphery of their embedding domain (e.g., main clause, argument NP), so as to avoid possible discontinuity among other constituents of the embedding domain.

The notion 'domain' stands for an integral, hierarchically organized linguistic unit and can be regarded as the functional equivalent of 'constituency' in syntactocentric theories of grammar. The PDI is perhaps the most obvious interpretation of Behaghel's first law and accounts for the fact that discontinuity is a marked phenomenon in languages across the globe. This principle sums up ideas that have been proposed in various forms, namely that constituents belonging to the same conceptual or semantic unit (for instance, because they help to describe or refer to the same object or event) are processed faster and easier when they appear in a continuous, uninterrupted sequence. Some languages, such as the western Austronesian languages, do not allow discontinuous phrases at all, but when a language does allow a constituent to appear outside the boundaries of its proper linguistic domain, this is commonly due to some pragmatic factor (e.g., contrastive focus) or complexity ('heaviness'). For example, in Ngiti (Zaire) highly emphasized numerals may appear in clause-initial position (Kutsch Lojenga, 1994, p. 355).

Ngiti

22. [*árù*]$_{num}$ *ma* *m-ɔ̀kɛ̀rɛ̀* [*itsu*]$_{NP}$
    eight 1.SG SC-cut:PERF.PRES tree
    'I have cut EIGHT trees'

In Dutch 'heavy' adnominal modifiers, such as relative clauses, may appear in clause-final position:

Dutch

23. *Ik heb net* [*de man*]$_{NP}$ *gezien* [*die gisteren mijn fiets gestole heeft*]$_{Rel}$
    I have just the man seen who yesterday my bike stolen has
    'I just saw the man who stole my bike yesterday'

Since appositional constituents are not part of an integral domain, it is less unusual for them to appear discontinuously (see the Introduction). It appears that loose, appositional relationships between constituents that together form a conceptual or semantic unit historically precede the employment of hierarchically organized linguistic domains (Van de Velde, 2009).

Head Proximity

The PHP basically states that languages prefer to have a short distance between lexical heads of hierarchically ordered domains (e.g., between head 'N' of subordinate domain 'NP' and head 'V' of superordinate domain 'clause').

24. Constituent ordering rules conspire to keep the heads of different, hierarchically ordered domains as closely together as possible.

This general ordering principle is based on the processing strategy, which basically holds that domain identification (e.g., of a clause or NP) plays a central role in language processing. One of the most reliable strategies to identify a linguistic domain is to find the constituent that is the head of the domain, because the head is typically (1) the only obligatorily constituent in a domain and (2) the most informative constituent of a domain. In languages that have distinct classes of verbs and nouns, verbs typically serve as the head of a clausal domain and nouns as the head of a phrase (incl. prepositional phrase; notice that adpositions are not regarded as heads in e.g., Functional (Discourse) Grammar).

The PHP could account for several ordering phenomena (Rijkhoff, 2004, pp. 261–312), including some of the constituent order correlations observed in Greenberg (1963) and Dryer (1992), such as (notice that, due to the pragmatic status of Subject, SVO languages are comparable to V-initial languages regarding head proximity; see Rijkhoff (1986, pp. 1–12 for details):

- the tendency to avoid embedded domains (like relative clauses or genitives) appearing between the head of the clause V and the head of the phrase N (cf **Table 1** and Dryer's *Branching Direction Theory*; dots symbolize adnominal modifiers);

25. a. V $[N....]_{NP}$ .... (verb-initial)
    b. .... $[....N]_{NP}$ V (verb-final)

- Greenberg's Universal 16 (see the Section Constituent Order Correlations):

26. a. Aux V .... (verb-initial)
    b. .... V Aux (verb-final)

- Behaghel's (1932) *Gesetz der wachsenden Glieder* ('law of growing members'), according to which long constituents in the clause appear at a greater distance from the head of the clause V than short constituents, which would result in a better overall ratings in terms of 'head proximity.'

27. Aux V $[...]_{NP}$ $[....]_{NP}$ (verb-initial)

Notice, however, that in terms of head proximity the long-before-short order is preferred in verb-final languages:

28. $[....]_{NP}$ $[...]_{NP}$ V Aux (verb-final)

While it is true that some verb-final languages have a preference for 'long-before-short' (Hawkins, 1994, p. 152), which is preferred in terms of head proximity, the structure in (28) also shows that in verb-final languages the PHP is in conflict with Behaghel's *Gesetz der wachsenden Glieder*, which predicts a general preference for short-before-long. This fundamental conflict between the two ordering principles could explain why so many verb-final languages are also characterized as 'free word order' languages, as there is often no clear statistical preference for a 'basic word order' in these languages. This conflict may also be the reason why some verb-final languages allow constituents to appear after the verb (also known as 'leaking').

The constituent orders exemplified in (27) and (28), i.e., short-before-long in verb-initial and SVO languages and long-before-short in verb-final languages are also predicted as the preferred patterns by Hawkins's *Principle of Early Immediate Constituents*, which says that structures with shorter recognition domains are easier to process (a detailed comparison between the *Principle of Head Proximity* (PHP) the *Principle of Early Immediate Constituents* and the *Branching Direction Theory* can be found in Rijkhoff (2004, pp. 261–312); see also Song (2009) and Song (2012, pp. 234–303). Hawkins's *Principle of Early Immediate Constituents* is similar in spirit to the PHP with regard to ordering preferences among short and long constituents in a sentence, but the PHP seems to cover more ground in that it could also account for certain seemingly disparate grammatical phenomena, in addition to the ordering tendencies mentioned above. For example, one could regard the two following phenomena as strategies that reduce the overall ratio of $head_N$-to-$head_V$ proximity in a clause (Rijkhoff, 2004, pp. 311–312).

1. Keep the number of NPs in a clause to a minimum: the fewer the number of NPs in a clause, the better will be the overall head proximity ratio. This can be seen in Cayuga and other polysynthetic languages, where ordinary discourse can consist largely of verbs.
2. Increase the number of verbs in a clause: the more lexical verbs a clause contains, the shorter will be the overall distance between heads V and N. This is exemplified in the Papuan language Kobon: if a sentence would contain many arguments and adjuncts, speakers have a strong tendency to divide them over two or more clauses (which may contain an identical predicate) rather than including them all in one sentence.

Scope

The PoS states that differences in scope among modifiers in a certain domain is iconically reflected in the actual linguistic expression:

29. Modifiers tend to occur next to the part of the expression that they have in their scope.

Scopal relationships between modifiers in a domain can be captured in meaning-based, layered representations of linguistic expressions as employed in, for example, Van Valin's (1993) *Role and Reference Grammar*, Dik's (1997) *Theory of Functional Grammar* and its successor *Functional Discourse Grammar* (Hengeveld and Mackenzie, 2008). In a layered representation it is clearly indicated which part

('layer') of a domain is within the scope of members of a certain functional modifier category. As was shown in (16), at least the following functional modifier categories can be used to analyze both NPs and clauses (Rijkhoff, 2008a, 2008c): (1) CLASSIFYING MODIFIERS, (2) QUALIFYING MODIFIERS, (3) QUANTIFYING MODIFIERS, (4) LOCALIZING or ANCHORING MODIFIERS, and (5) DISCOURSE-REFERENTIAL MODIFIERS.

Modifier categories include both grammatical and lexical elements (cf (16)), covering all the 'dependents' in a domain that are not arguments or complements. In a formal, meaning-based representation, these modifiers are distributed over 'nested' layers around the head constituent, reflecting differences in semantic scope. Conventionally, grammatical modifier categories (LOCALIZING/ANCHORING MODIFIERS such as demonstratives or tense markers) are represented on the left, whereas lexical modifiers (e.g., QUALIFYING MODIFIERS in the form of an adjective, a prepositional phrase, or a relative clause; see **Table 4**) are represented on the right. The various layers are shown in a strongly simplified form in **Figure 1** (notice that clauses have at least two more outer layers of modification to accommodate propositional and illocutionary modifiers; see Van de Velde, 2012 on NP internal mood).

The iconic relationship between the distance of a functional modifier category relative to the head in the layered representation of a linguistic expression and constituent order is most clearly seen in the case of simple (nonphrasal) modifiers in the NP, because here the PoS does not compete with Domain Integrity (Section Domain Integrity), which says that the preferred position of an embedded domain (e.g., Genitive, Relative Clause) is in the periphery of its embedding domain. Behaghel's (1932) *Gesetz der wachsenden Glieder* ('law of growing members') is another competing ordering principle that is relevant here (see above). Furthermore, embedded domains tend to be more versatile in functional terms than non-embedded domains (section 'Same Constituent, Different Functions'; Rijkhoff, 2009b). On the assumption that deictic adnominal demonstratives (dem) typically serve as LOCALIZING/ANCHORING MODIFIERS, cardinal numerals (num) as QUANTIFYING MODIFIERS, and genuine, nonderived adjectives (A) as QUALIFYING MODIFIERS, there are 24 logically possible combinations in an NP where the noun is modified by a member of all three modifier categories (as in English 'those three black boxes'). Only eight of these ordering patterns iconically reflect scopal relations among the three modifiers and it appears that each of these 'iconic' constituent orders is attested (Rijkhoff, 2008b, p. 802):

30. dem num A N (Dutch) — num A N dem (Berbice Dutch Creole)
    dem num N A (Spanish) — num N A dem (Hmong Njua)
    dem A N num (Zande) — A N num dem (Sango)
    dem N A num (Bambara) — N A num dem (Oromo)

In each ordering pattern in (30) the adjective is adjacent with the noun and the demonstrative is in the periphery, mirroring the layered representation in **Figure 1**. It has been argued that claims about the occurrence of noniconic patterns only constitute apparent counterexamples, because in such cases at least one of the following statements is true (Rijkhoff, 2004, pp. 272–273; 2008b):

31. a. constituents treated as semantic numerals or adjectives are formally speaking embedded domains headed by stative verbs or abstract nouns (see the Section Domain Integrity and heaviness);
    b. constituents are expressed as bound rather than free elements, which means their expression is a matter of morphology rather than syntax (Section Investigating Constituent Order Across Languages: Some General Issues);
    c. constituents are in apposition (rather than fully integrated constituents; see the Introduction).
    d. constituents are assigned a special pragmatic function like Focus, indicating we are dealing with a marked pattern (see, for example, the marked position of adjectives in Hungarian NPs).

Recently Cinque (2005) has argued that 14 orders are attested: the eight iconic patterns listed in (31) plus the six noniconic ones in (32). Interestingly, the noniconic orderings only involve postnominal modifiers (cf. the Introduction on apposition):

32. dem N num A — A N dem num — N dem A num
    N dem num A — N A dem num — N num A dem

However, since Cinque (2005, p. 315) employed semantic criteria to identify constituents (section 'The Employment of Semantic Criteria in Constituent Order Research'), he also included constituents that are characterized by one or more of the properties listed in (31). For example,

Figure 1 Some functional modifier categories in a layered representation of NP/clause structure reflecting differences in scope (Rijkhoff 2008a, 2008c).

- in Arbore (Cinque: N dem num A) demonstratives are suffixes and numerals are regarded as a subset of nouns;
- in Sampur (Cinque: dem N num A) adjectives are basically verbs heading a relative construction.

In sum, when we exclude apparent counterexamples like those mentioned under (31), it remains to be seen how many noniconic ordering patterns in (32) actually occur (in fact, there are just a handful of languages with noniconic orders in Cinque's study).

Arbitrary Patterning

Notice finally that even noniconic or 'arbitrary' ordering patterns can aid in language processing. Any consistent form of linear organization can be used to structure discourse. For example, speakers of the Peruvian language Iquito mark the distinction between REALIS and IRREALIS clauses solely by means of word order constraints (Beier et al., 2011). It is easier to identify constituents and process the linguistic expression they are part of when constituents with the same functional specification occupy the same position in a linear structure. Thus, whether a language has OV or VO order is essentially arbitrary, but knowing that one's language normally has the object argument before the verb provides the language user with interpretation or decoding strategies. Similarly, whether a language has AN or NA order is essentially arbitrary, but knowing which order is used in a language facilitates information processing.

Abstract

The sociology of work and industry studies the patterning of work activities and work-related institutions in industrialized societies, taking into account ongoing changes in technology, global relations, labor markets, work organizations, managerial practices, and employment relations. It observes the ways in which these changes are related to patterns of inequality in modern societies and to the experiences of individuals and families as well as the ways in which workers challenge, resist, and make their own contributions to the shaping of social worlds. These concerns are consistent with but more extensive than what was previously labeled 'industrial sociology.' This term is currently rarely used. The former industrial sociology's essential concern with the social implications of industrialization can nevertheless be carried forward within a coherent but expanded 'sociology of work and industry.'

Beyond 'Industrial Sociology'

The most obvious reason to use the term 'the sociology of work and industry' rather than 'industrial sociology' is that the latter term is nowadays rarely used. There are various factors contributing to this change. At the heart of it is a shift of focus onto 'work' rather than on undertakings which might be labeled 'industrial.' This has come about for a further variety of reasons. Especially significant is the fact that erstwhile industrial sociologists have, in recent decades, become increasingly sensitive to gender aspects of social life and have recognized that a great of vital laboring effort is expended, especially by women, outside formalized 'industrial' workplaces. Reinforcing this trend has been a reluctance to analyze nonfactory-like workplaces such as medical centers, charities or sports clubs in the same way that industrial undertakings tended to be analyzed.

Although some writers have suggested that contemporary society is somehow 'postindustrial,' there are still grounds for the retention of the adjective 'industrial' in the field of study with which we are concerned given that the societies which are studied have all at some time become industrialized or, alternatively, are facing the prospect of industrialization in the future. We might further note that the term 'industry' has by no means disappeared from everyday language. It is not only used to refer in a generalizing way to an institutional slice of society ('the industrial sector') but to particular areas of formal economic activity – the retail industry, the agricultural industry, creative industries, the leisure industry, the car industry, the mining industry, and even the education industry and the health industry. Some of these expressions may be more amenable to sociological use than others. Sociologists of work have made valuable contributions to our understanding of the growing 'creative industries,' for example, in a way perhaps not significantly different from the way industrial sociologists used to write about the mining industry. What is important, however, if we are going to retain a notion of 'industry,' is that we go beyond a focus on the factory which the descriptor 'industrial' has tended to connote (together perhaps with extractive and transport undertakings). It is interesting to note that in the previous edition of the *International Encyclopedia of Social and Behavioral Sciences*, Berg wrote that "Industrial sociology denotes the systematic study of the cultural and historical forces that foster the development of manufactories, and the diverse organizational structures, infrastructures, and market structures with which this development is associated" (Berg, 2001: p. 7351; my emphasis).

Berg's chapter on industrial sociology has a valuable historical emphasis and her emphasis on the centrality of the factory to processes of industrialization is undeniable. It should remind us that the factory is still a highly significant aspect of people's working lives, if we look at work across the world. Such a global perspective also shows that the work carried out by women and men in less developed economies has important implications for the work and lives of people located in the vastly more affluent societies with which these establishments are intimately involved. But many contemporary sociologists of work would argue that, even with the long and hard hours worked in factories of developing economies, work for people in these establishments, life-dominating as they appear to be, remains an activity to be carried out in and around the home as well as at the rows of machines in giant manufacturing sheds. It is reasonable to speculate that the acceptance of this fundamentally important insight not only results from the growing gender-sensitive nature of contemporary sociology mentioned earlier but also from a growing interest among sociologists in human beings not just as members of social categories (factory worker, accountant, nurse, say) but as 'whole persons,' with biographies, homes, sexualities, and ethnicities, as well as particular 'jobs.'

An interest in looking beyond simple job categories was present within the older industrial sociology tradition but is now an increasingly central feature of research in the newer and broader sociology of work tradition, an enterprise which combines a concern with global and societal shifts in working patterns with an interest in the lives of the people caught up in such shifts. This trend can be interpreted as one in which sociologists are fulfilling, whether consciously or not, the promise implicit in Mills' notion of the *sociological imagination*, with its call for social scientists to examine the connections between the 'patterns of people's own lives' and 'the course of world history' (1970: p. 9). This would mean that a study of

people engaged in, say, unpaid 'intern' work roles would bring together an analysis of changing global and societal patterns in such things as labor flexibility, employer power, roles of trade unions and professional associations, and legal regulation with attention to the implications for different individuals undertaking these roles, in light of their particular class and educational background, gender, ethnicity, and self-identities.

Changing Conceptions of Work

The trends identified so far in the development of the contemporary sociology of work and industry all raise important questions of just how sociologists might most usefully conceptualize 'work.' From what has been observed so far, it is clear that we are seeing a broadening of the 'work' category of human activity. Industrial sociologists tended simply to regard work as the task-based activities for which people are paid by an employer, client, or customer. This is a conception of work which is often used in everyday conversation when, for example, people are referred to as being 'in work' or 'out of work.' But difficulties can arise in such conversations as in the following ethnographic snippet:

> I hear you retired earlier in the year.
> Yes, that's right. It's really nice not to get up early every morning to drive to work.
> But don't you miss work?
> Well, not really, I'm working as a volunteer in the local library two days a week. And I must admit that we neglected our garden for years. It's taking an awful lot of work to sort it out.

This is a perfect parallel with the dilemma facing sociologists of work and industry who, if they did not broaden what is to be treated as work, would have to ignore activities which people still regard as 'work,' even though they involve no wage, salary, or fee. However, sociologists of work are increasingly anxious not to ignore unpaid activities which involve the completion of tasks through the expenditure of labor. Some researchers have gone as far as suggesting this broadening of our conceptions of work in creating a 'new sociology of work' (Pettinger et al., 2006). These researchers are significantly influenced by Glucksmann's (2006) concept of a 'total social organization of labor' (TSOL).

A TSOL approach, or something like it, studies the ways in which "all the labor in a particular society is divided up between and allocated to different structures, institutions and activities" (Glucksmann, 2005: p. 67). Thus, if we were to look at a society in which bread is important in people's diets, we would not only consider the historical and cultural context of bread production, we would go on to look at the various ways in which bread is produced across the society as a whole (and perhaps beyond) – some in factories, some in bakers' shops, some in homes, and some in groups of baking hobbyists – all the time relating these activities to patterns of class, gender, taste, income, and so on. The fact that it is often difficult to distinguish which are work activities and which are 'nonwork' activities is not a problem to a researcher adopting a perspective of this kind. We might ask, for instance, whether or not we should regard as 'work' the hours of effort expended on restringing all the guitars of an amateur guitar band undertaken by one member of that band. This is not, however, something to worry about unduly. We would be better considering how the members of the band themselves regard this task and asking just how this particular task allocation came about. The fact that there are often blurred lines between work and nonwork is something to examine in any particular research situation. Despite this, it is helpful to take as a starting point for research in the sociology of work and industry a basic concept of 'work.' This would retain the notion of task-based activity and would combine this with the notion of the shaping of people's lives. Thus, we can usefully conceptualize work as the carrying out of tasks which enable people to make a livelihood, in the sense of economic well-being, the maintenance of social relationships, and the achievement of a coherent sense of self.

The concept of work suggested here entails attention to an enormous range of topics and issues. To map this territory, it is helpful to divide researchers' and theorists' interests and activities into five subterritories or dimensions of the sociology of work and industry.

Major Dimensions of the Sociology of Work and Industry

Work and Global Social–Political–Economic Change

The discipline of sociology emerged as an intellectual reaction to the massive changes in European societies (Nisbet, 1970) brought about by the sixteenth-century Reformation, the seventeenth- and eighteenth-century Enlightenment, and the late eighteenth- and nineteenth-century Industrial and French Revolutions which further shook and often overturned these institutions. Industrial sociologists focused on the industrialization element of these changes but, true to their sociological priorities and their reliance on the powerful analyses and critiques of Durkheim, Marx, and Weber, they showed how the massive expansion in the use of emerging complex technologies, bureaucratic structures, and large-scale concentrations of workers in and around factories could only be understood as part of fundamental changes in the societal distributions of power and the cultural and economic shifts coming about with what Weber called a 'spirit of capitalism.'

Sociologists continue to debate on the extent to which the form of industrial capitalist society which emerged in the nineteenth century and came to dominate large parts of the world in the twentieth century is being superseded by, for example, postindustrial or postmodern societies. Sociologists of work and industry played their part within wider debates while focusing in particular, we might say, on the ways in which the division of labor is changing in the world. This builds on the concerns of the key figures of early sociology. The two most important contributions here were, first, Durkheim's (1984) recognition that the division of labor of a society was central to its form of social solidarity ('mechanical' in societies with simple divisions of labor and 'organic' in societies in which solidarity came about through the interdependence of a multiplicity of occupations in a society). Second, we have Marx's distinction between

a social division of labor, where work tasks are allocated at the level of society into occupations and trades and a technical division of labor in which specialization occurs within an occupation or broad work task. Durkheim's concerns are central to the current interest in 'professions' while Marx's analysis is vital to the notion of the 'capitalist labor process' which is used in the study of a considerable range of work activities and managerial arrangements observing its distinctive approach to the design, control, and monitoring of work tasks and activities by managers acting as agents of the capital-owning class in order to extract surplus value from the labor activities of working people.

In studying changing divisions of labor in contemporary times, particularly in the light of rapidly changing information and computer technologies, considerable attention has been paid to the role of knowledge or 'information,' with modern societies sometimes being characterized as information or network societies (Castells, 2000). Different, but not unrelated, is the changing balance between manufacturing work and service work with some researchers utilizing a novel concept of the McDonaldization of work (Ritzer, 1993). This deals with the way in which industrial manufacturing (or 'Taylorist') principles of deskilling, mechanization, and rationalization are applied, not just to fast-food businesses but to work in retailing, banking, and many other 'service work' areas of employment.

The changes in social organization which brought into being both the institutions of industrialism and the discipline of sociology began in Europe but have implications now for almost every part of the world. The much contested concept of *globalization* has emerged as part of intellectual attempts to make sense of this development. Perhaps the simplest way to understand 'globalization' is to treat it as general trend in which the political, economic, and cultural activities of people in different parts of the world increasingly influence each other and become interdependent. The sociology of work and industry, with its roots in the thinking of the classical sociologists who first struggled to come to terms with European industrialization and its accompanying transformations, is now coming to terms with changes and trends on this much larger scale.

Work Organizations

If we build upon the insights into changing divisions of labor associated with industrialization introduced by Durkheim and Marx, it is possible to suggest that there are two fundamental principles of work structuring in industrialized societies. One is the occupational principle of work structuring (to be considered later) and the other is the organizational principle in which work is patterned as the outcome of institutional arrangements in which some groups of people conceive of and design work and then recruit, reward, coordinate, and control the efforts of other groups. Sociological study of work organizations not only examines them as parts of the wider social organization of societies, it also recognizes that organizational structures involve a great deal more than the formal arrangements represented by managers' organization charts, rules books, and operating procedures. This accords with Weber's emphasis on the unintended consequences of human social actions and means that unofficial/informal aspects are studied alongside official or formal arrangements. Despite the power of such ways as looking at organizations, certain writers have argued that postbureaucratic organizations are now emerging. These are variously characterized as 'entrepreneurial,' 'networked,' or 'culture-led.' Sociologists have reacted to this type of thinking by arguing, in effect, that although there may be new variants of bureaucracies appearing, this does not warrant a denial of analyzing such arrangements as bureaucracies (e.g., Reed, 2005).

Sociologists generally are continuing to develop forms of analysis which give balanced attention to human agency and to the structural and cultural circumstances, and contingencies which both constrain and enable human initiative taking in the organizational setting. This has been reflected in a shift of emphasis by sociologists of work and industry away from the so-called contingency theory in which an organization's contingencies were, implicitly at least, seen to determine organizational forms to one in which the contingent circumstances of any organization (such as its ownership, market circumstances, technology, and type of people employed) are recognized as being mediated by the 'strategic choices' made by managers (Child, 2005). Yet these managers are by no means members of unified groups, as is demonstrated by studies of organizational *micropolitics* (Burns, 1961). Managers are frequently in competition with each other in their careers and researchers adopting a *negotiated order perspective* (a notion beginning in the symbolic interactionist theoretical tradition; Strauss, 1978) apply this insight much more broadly. Negotiated orders are the patterns of activity emerging over time in an organization as an outcome of the interplay of the various understandings, interests, initiatives, and reactions of the individuals and groups (including and beyond those of managers) who are involved in that organization.

It is within this broad theoretical emphasis, together with a strong interest in cultural as well as structural aspects of organizations, that sociologists of work and industry have examined changing managerial and corporate initiatives in the managing of work organizations. The work of sociologists studying work and work organizations has often been inspired by a perceived need to counter the assumptions and analyses of managerial thinkers and practitioners, this perhaps most famously occurring with the investigations made at the Hawthorne plant of the Western Electrical Company in Chicago in the 1920s and 1930s (Roethlisberger and Dickson, 1939). These investigations countered the assumptions and recommended practices of the 'scientific management' movement or 'Taylorism' (Taylor, 1911). The spokesperson of the counter movement, the so-called human relations school, inspired by the Hawthorne studies, was Elton Mayo, an individual influenced by Durkheimian thinking. But where Durkheim hoped for the achievement of 'social integration' through an emphasis on occupational moral communities, Mayo looked to work organizations and, especially, to work groups for the fostering of positive social sentiments and moral stability in society.

This broadly critical role for the sociology of work and industry continues to be significant as it relates a variety of corporate and organizational initiatives to broad processes of *work restructuring*, in which patterns of work experience,

organizational, and occupational activity change as part of the general economic, political, and cultural shifts occurring across the world. This again involves countering such discourses as those of team working, lean production, delayering, flexible working, and a managerialist 'human resource management.' Research shows that high commitment/indirect control human resourcing and work design practices (using an organic or flexible bureaucratic style) are not the outcome of a straightforward 'progressive' movement among employers which will simultaneously achieve greater business effectiveness and all round fairness, as much 'Human Resource Management' writing implies. Managers, in fact, are equally ready to pursue rigidly bureaucratic low-commitment and direct control practices when the circumstances allow it (say when they are using a simple technology requiring low worker skills in a context of low-state regulation of employment practices).

Occupations and Occupational Structure

The work organization dimension of the sociology of work and industry outlined earlier deals with one of the two main principles of work structuring operating in industrialized societies: the organizational principle, with bureaucracy (which might be relatively rigid or relatively flexible) at its heart. Industrialization, the bureaucratizing of work and the shift to a complex technical division of labor, has increasingly dominated sociological analysis of the organizational principle. But it has not totally supplanted attention to the second principle. This is the much older occupational principle of work restructuring, the principle underlying the social division of labor (Marx) or the mechanical division of labor (Durkheim). Analyses of aspects of the occupational principle concentrate on the ways in which particular work tasks are done, taking as a starting point the carrying out of a particular type of work activity such as building houses, running businesses, driving taxis, or catching fish. Attention is then paid to the implications for workers and society of the existence of groups of people regularly undertaking similar tasks.

Because a person's occupation generally plays a part in their economic position and their social status, the sociological study of occupations necessarily links strongly with the sociology of inequality. It examines how continuous shifts in the social division of labor affect the life chances of people in particular occupations. In particular, close attention is paid to trends of market segmentation and occupational areas that associated with nonstandard or 'contingent' employment including part-time and temporary work, home-working and 'teleworking.' But there are also occupations which do not involve employment. Hence sociologists of work are increasingly looking at self-employment, work in the informal economy, domestic work, and 'volunteering.' Connected to all of these, and also more broadly, are questions of gender inequality, and sociologists of work often combine their research efforts with researchers who have a primary interest in gender matters. The same point applies to issues of ethnicity and work.

A long tradition in the occupational dimension of the sociology of work and industry is that of the in-depth study of specific occupations including managers and supervisors; knowledge, cultural, and creative workers; and 'dirty' or deviant occupations like prostitute, mortuary attendant, and drug dealer. When particular occupations are studied, the sociology of work has a range of occupational features to examine: processes of occupational recruitment and socialization; occupational careers; and occupational identities, occupational cultures, ideologies, and occupational communities. In the study of all of these, especially with regard to newly emergent occupations, the sociological perspective encourages the linking of occupational matters to changes covered in the dimensions of the sociology of work and industry reviewed earlier. This is especially the case with the extent to which occupational members may organize themselves to gain the relative autonomy associated with occupations having undergone or undergoing 'professionalization.'

Work Meanings, Experiences, and Identities

Throughout the history of the sociology of work and industry, with its roots in concerns about social transformations, attention has been paid to the fact that just what work means to people in their lives, varies from one historical period to another, from one society to another, from one occupational or organizational setting to another. Weber's concern with the protestant ethic and the spirit of capitalism mentioned earlier is clearly an inspiration here at the broader societal level. Moreover, a general social concern inspired, in the twentieth-century sociology of work, studies of worker *job satisfaction* and its opposite *worker alienation*. From the 1960s, these issues tended to be conceptualized in terms of people's *work orientations* (Goldthorpe et al., 1968), this shift being inspired by sociologists' dissatisfaction with the reductionist and often managerially biased psychologistic notion of 'work motivation.' This saw a shift toward studying the meanings that people attach to their work in the light of how they are managing their whole lives and its value lies in the way it connects issues in personal lives and social circumstances to the ways in which they think about and act in the work setting. This is fully in the spirit of the sociological imagination, linking the personal to the organizational and occupational and, indeed, to the societal. It also fits with the trend toward achieving a balance between attention to 'agency' and to 'structure' in sociology generally.

In the past two or three decades, the insights of the earlier shift of focus toward work orientations has been further developed by a strong concern with the connections between work and *identities* – the category of 'identity' covering both the *self-identities* (individuals' own notions of who and what they are) and *social identities* (cultural, discursive, or institutional notions of who or what any person might be). Human beings are seen as continually 'working' on their notion of self – doing *identity work* (Watson, 2008) – in part through a cognitive dialog with the discursive resources available or imposed upon them by the social world in which they live – notions of what a manager is, what a police officer, a waiter, a retail worker, a sex worker is. Research is increasingly showing how complex these processes are in the light of various ambiguities, stresses, tensions, and contradictions inherent in different work roles. Attention is increasingly paid to emotional aspects of work (including the part played by sexuality in the workplace). Recent research has examined the distinctive pressures on people involved in 'aesthetic labor.' Alongside these recent

developments, attention continues to be paid to long-standing concerns of the sociology of work such as to the changing ways in which people relate their working and their nonwork lives and to the people's experience of unemployment.

Conflict, Challenge, and Mischief at Work

Work organizations are not big consensual human machines rationally and neutrally directed by their designers and managers. They are settings in which there are multiple and often competing interests. This view is vital to the concept of the work organization as a negotiated order, a notion which was introduced earlier. The implication of this is that conflict will be ever present in workplaces alongside, and in tension with, the cooperative efforts without which the organization or workplace would not continue to exist. The conflict aspect of work arrangements and activities generally thus runs through all the dimensions of the sociology of work and industry. It is nevertheless helpful to treat the study of conflict and challenge as a dimension of the sociological study of work in itself. One immediate justification of this lies in recognition of the trend whereby specialist academic disciplines such as 'industrial relations' or 'employment relations' have tended be subsumed into work sociology, something which might be welcomed as bringing a much fuller contextualizing perspective to studies of the collective organization of workers and their bargaining with employers. The benefit of this is apparent in studies which examine the reducing influence of trade unions in societies, something inevitably related to the world changes and processes of globalization. Also, by bringing into analyses the concepts of contradiction, paradox, and unintended consequences of classical sociology, stronger light can be thrown onto the innovations and adaptations in work activity regulation following the reduction in the influence of traditional trade unions.

Given the pervasiveness of conflict of interest and orientation in workplaces, it has been wholly inadequate to attempt to study these within the frameworks of industrial and employment relations. Many of the challenges presented to those in charge of work operations arise from individuals – sometimes alone, sometimes in small groups – asserting their interests, their relative autonomy, their pride, and their sense of 'self.' Notions such as 'organizational misbehavior' (Ackroyd and Thompson, 1999) or 'organizational mischief' (Watson, 2012) have usefully pulled together the considerable range of activities in workplaces which, first, should not happen according to the official rules and structure of the workplace and, second, contain an element of challenge to the dominant interests of those in charge of the work organization. This type of framework can incorporate the long-standing industrial sociology interest (originally in the Hawthorne studies mentioned earlier) in how workers develop job control strategies and 'make out' in the light of managerial efforts to control them. Studies regularly appear of the role that humor plays in the workplace; the causes and consequences of sexual harassment and bullying; fiddling and cheating; and sabotage, rule manipulation, and 'defense of self' tactics developed by service workers in the light of the potential subservience and humiliation involved in serving customers or clients.

Conclusion

In the world of academic endeavor, as in the physical world, it is not possible to create a single, objective map of any given territory. The best one can do is to offer a map of the territory which the map-maker feels is the most useful one possible for the map-reader. The present chapter's mapping of the territory of the sociology of work and industry, with the utilizing of the notion of five 'dimensions,' has been produced in this spirit. Underlying the accounts of the various dimensions of the sociology of work and industry is the argument that they are unified and integrated by their application of the sociological imagination to the task of intellectually coming to terms with, and offering insights to the nonacademic public with regard to, the tensions and difficulties created for individuals and societies of living in an industrialized world.

This article is a revision of the previous edition article by G. Spittler, volume 24, pp. 16565–16569, © 2001, Elsevier Ltd.

Abstract

Work encompasses direct subsistence pursuits, paid employment, and other activities contributing to survival and enhancement of individual and group life. Such efforts may be coerced, onerous, and deficient in rewards, but they can also bring fulfillment. Assumptions and conceptual breakthroughs that have shaped the study of work within anthropology are outlined. Work is identified as a prominent theme in classic ethnographic accounts. The genealogy of anthropological research more explicitly focused on work is traced. Recent scholarship examining the margins of work at its intersections with unemployment, underemployment, and leisure is reviewed, along with reflexivity in the work of anthropologists themselves.

Disciplinary and Subdisciplinary Orientations

Anthropologists study work in many ways, often inadvertently while more concerned with other themes. Work encompasses direct subsistence pursuits and paid employment, along with other activities contributing to survival and enhancement of individual and group life. While the efforts may be coerced, onerous, and deficient in rewards, they can also bring fulfillment. Much of what people think and do is affected by understandings, intentions, and identities derived from work. Considering all aspects of work, anthropologists address fundamental attributes of what it means to be human.

This article begins by outlining assumptions and conceptual breakthroughs that have shaped the study of work within anthropology. Next it explores treatments of work as a prominent theme in classic ethnographic accounts. The discussion traces the genealogy of research more explicitly focused on work, expanding and deepening our understanding of its centrality in social life. A survey of the current proliferation of literature is not possible, but major topics are identified. Much recent scholarship examines the margins of work at its intersections with unemployment, underemployment, and even leisure. Concluding remarks integrate the reflexivity that arises when the analytical framework extends to the work of anthropologists themselves.

Terminology

Given the pervasive and varied uses of the term, any attempt to define work narrowly would be futile. In an early delineation of the anthropology of work as a field of study, Sandra Wallman (1979) grounded work in energy expenditures, including thoughts ('psychic energy'), which produce both material and immaterial things of value. This and other behavioral criteria lay a foundation for the anthropology of work, but additional considerations are necessary to specify why certain activities in which people engage in a given setting are considered work and others are not.

What meanings do anthropologists apply to work and related terms? In English, *labor* usually contextualizes work socially. As indicated by its use for the birthing process, labor refers to biological as well as social reproduction. In this article, the focus is on work but with labor always part of the picture. Thus, *employment* is a condition of labor rather than work as such. *Occupation* and *livelihood* are terms, which reflect configurations of productive pursuits with some degree of social integration and permanence. *Career* is a problematic designation for conglomerations of roles conveying a sense of continuity, identity, and competence. Anthropologists have used this term to refer to the work of self-sufficient food collectors and food producers as well as individuals and groups in technologically advanced societies with complex divisions of labor (Goldschmidt in Gamst, 1995; Orr, 1996).

Whether work entails direct inputs to survival and well-being through *production* and *exchange* of goods and services or through less direct forms of *reproduction*, it involves culturally specific overlays on more fundamental pursuits. For example, consumption practices may blur the boundary between work and leisure, as with shopping, which may be a recreational pastime. This raises the inferential problem of cognitive criteria in relation to observable behavior. Ambiguities and nuances in terminology are illustrated below by examples, which interrelate the personal, interpersonal, behavioral, and institutional aspects of work.

Anthropological Departures

Anthropology's scientific (and humanistic) legacy of understandings about work draws from three conceptual domains, arguably fostering more holistic approaches than are usually encountered in other disciplines. The first is *natural economy*, an evolutionary construct for distinguishing degrees of local self-sufficiency based on use values, including vestiges of domestic modes of production in the present day. The second, *political economy*, concerns power relations that shape and are shaped by access to and control of resources, labor (and labor markets) in particular. The third, *moral economy*, pertains to ethical, spiritual, and legal codes that influence work through ideas about obligations, justice, and ultimate ends. Anthropologists have been in the forefront in documenting and assessing the local implications of the global integration of these three dimensions of economic life (e.g., Narotzky, 1997; Collins, 2003; Hakken, 2003).

Eric Wolf's (1983) ironically titled and frequently cited *Europe and the People without History* can be read as a comparative

analysis of the incorporation of localized and regionally connected labor regimes in the making of the modern world. Synthesizing ecology and political economy in his analysis, he shows how the (re)organization of work and expropriation of labor in widely dispersed zones with different kinds of resources were crucial to European colonial expansion and the development of capitalism. Wolf's global ethnohistorical survey highlights the centrality of work in processes of change in forms of culture, which he defines as social constructions built up from forces generated through established ways of mobilizing social labor, i.e., *modes of production*.

Disputes regarding evolutionary versus historical change may conflate incongruent scales of time, space, and changing human–environment relationships. Although industrial societies were not neglected as anthropologists positioned themselves among other social and behavioral scientists studying work (Applebaum, 1984; Gamst, 1995; Mollona et al., 2009), anthropology has been characterized by a broader comparative interest in what it means to be human in all times and places. An archaeologist seeking evidence of livelihoods in two-million-year-old chipped stone tools can make common cause with an ethnographer who observes the tasks and interaction styles of computer hardware and software engineers. Anthropologists also have been attentive to current events, for example, through ethnographic research that illuminates the assumptions and practices of Wall Street traders that contributed to the financial meltdown of 2008. The context for anthropology of work in recent years has been the neoliberal world economy and the precarious labor market that is one of its defining characteristics.

Although most anthropological research about work has been ethnographic, understanding of the multiple facets of work is strengthened when the concerns and expertise of more than one subdiscipline are brought to bear. Biological anthropologists have examined anatomical and physiological correlates of work in terms of energetics and health indicators. Physical structures and capacities of the human body, beyond their original importance in the course of human evolution, remain a factor in ongoing cultural change. Archaeologists encountering the material remains of work cannot directly answer questions about associated behavior patterns and meanings. However, from one era to another in any given area, similarities and differences in flora, fauna, raw materials, tools, and work sites generate insights about continuity and change in subsistence patterns and other features of economic life. Archaeologists who design their investigations of wealth and power in relation to production, exchange, and consumption can trace continuities and discontinuities in the political economy of work as well. Stylistic analysis, yet another avenue of archaeological investigation, offers otherwise inaccessible insights about the ways a distinctive *ethos* can shape work and its products over time.

Ethnographic Trajectories

Anthropology's long ethnographic tradition integrates the conditions, procedures, and products of work as parts of an entire way of life. These findings have enabled ethnologists – through comparative cross-cultural interpretations and explanations – to trace both recurrent patterns and significant discontinuities holistically. Work is a polysemic term. *Embodiment* refers to its physicality and its experiential aspects: the first in the neuromuscular manipulation of materials and tools, the procedures carried out, and the corporal effects of these efforts, and the second in the satisfactions, sufferings, struggles, and sense of identity of participants in work-related roles and activities. *Engagement* refers to the ways individual roles and interpersonal interactions are organized. Work rarely originates in isolation. Individuals benefit from preparatory nurturing and training, which applies not only to established routines – as with apprenticeship – but also to changes brought about by innovators and entrepreneurs. *Embeddedness* refers to the norms and social matrix that facilitate, constrain, and otherwise shape individual and group efforts. Economic anthropologists have long argued over the degree to which self-interest and rationality are culturally contingent, asking whether the meaning of work varies from one social context to another. Recent trends in the study of work have brought the subjective dimension to the forefront, building on a long tradition of biographical studies (e.g., Mintz, 1974 [1960]). Thus, the cumulative ethnographic tradition in anthropology has yielded richly nuanced descriptions, interpretations, and explanations of work.

Food Collection

Detailed ethnographic accounts of work appeared at least as far back as the depictions and explanations of arctic hunting by Franz Boas (1964 [1888]) in the late nineteenth century. By the mid-twentieth century, a sense of urgency propelled quantitative and qualitative research on the food quest of the few remaining small and relatively self-sufficient gathering and hunting societies in marginal habitats. This most basic human form of provisioning is often described as 'foraging,' but 'food collection' – whereby a few individuals split off in different directions to find and bring food and other necessities back to share with the rest of the group – differs fundamentally from the browsing and grazing of other species. The search for origins in the evolution of work in early human societies is distinct from arguments over historical continuities and discontinuities in structurally similar subsistence patterns occurring from ancient times into the recent past.

Gathering, Hunting, and Quality of Life in the Kalahari Desert. Among many fine-grained ethnographic accounts of food collectors, Richard B. Lee's 1979 study of *The !Kung San: Men, Women, and Work in a Foraging Society* (excerpted in Applebaum, 1984) stands out. Incorporating research strategies of biological anthropologists, Lee quantified the mix of tasks and considered the efforts expended in obtaining foods in relation to their nutritional values. Differences between the time spent by women gathering plant foods, and occasionally capturing small animals, and by men hunting larger game revealed a marked division of labor. The implications of this documentation are profound, both to discern a gender axis for assessing other elements of social organization and for inferences about cultural change. Men devoted more time to the food quest, but women spent more time on work overall, when other recurrent domestic tasks were taken into account. Lee found the rhythm of women's work steadier, distinguishing 'subsistence' (including travel) from 'manufacture and

maintenance,' 'child care,' and 'housework' (with cooking mostly done by women, for instance, but with larger game cooked by men). He decided not to categorize planning for the hunt as work, since reports of game sightings and consultation of oracles took place during the relaxation of pleasurable evening gatherings. While relevant to efforts to establish primordial baselines for work and leisure, this distinction is also useful for comparative discussions of the fuzziness of such boundaries in many settings today.

Evolutionary and Historical Perspectives. The much disputed assumption of an 'ethnographic present' beyond the here and now of a given study is relevant in the search for persistent features of the natural economy. To what extent, if any, can subsistence patterns documented in the mid-twentieth century be extrapolated as continuous from early human societies? At stake are not only debates about the significance of continuities in environmental relations and historical political economy, but also controversies over quality of life, cultural autonomy, and international human rights today (Povinelli, 1993; Narotzky, 1997; Lee in Nash, 1998; Gordon and Douglas, 2000).

Time allocation and health indicators among relatively autonomous gatherers and hunters raise questions about pressures and motivations for the development of food production systems. Evidence suggests that food collectors averaged fewer hours per day than members of agricultural and industrial societies in meeting their subsistence needs until population growth or displacement left them with an inadequate resource base (Johnson in Applebaum, 1984). Beginning in the second half of the twentieth century, however, indigenous peoples have been struggling to retain or regain rights to territories and subsistence regimes. For instance, 'labor action' by Belyun Aboriginal Australians, especially women, led to successful legal contestations of their land claims (Povinelli, 1993).

Food Production

Work has been central to major social transformations, none more momentous than the agricultural revolution. With the domestication of plant and animal species, greater productivity and population growth led to more competition for resources, increasingly complex settlement patterns, and corresponding institutional responses.

Gardening and the Work of Magic in the Trobriand Islands. Published in 1935, Malinowski's magisterial *Coral Gardens and their Magic: A Study of the Methods of Tilling the Soil and of Agricultural Rites in the Trobriand Islands* (excerpted in Applebaum, 1984) is an early, meticulous account of crop cultivation in Melanesia. It merits attention not only for the thorough descriptions of all the physical elements one would expect – soils, plants, tools, and techniques of horticulture – but also for Malinowski's intricately detailed explanations and interpretations of associated activities. From the perspective of a coherent anthropology of work, the ritual tasks of the specialist in magic who coordinates the work schedule are as relevant to the production process as physical manipulation of the environment (Spittler, 2008). Once crops are growing, as Malinowski puts it, "Nature now has to do most of the remaining work." In accord with Malinowski's functionalist theory, then, the magician's work parallels other tasks required to fulfill the population's survival needs.

Family Farming in Nigeria, Switzerland, and China. Robert Netting's *Smallholders, Householders: Farm Families and the Ecology of Intensive Sustainable Agriculture* (1993) surveys continuities and changes in the organization of agricultural work during the second half of the twentieth century in societies where marketing of crops and dairy products supplemented subsistence farming. Drawing on his own cultural ecology research in Nigeria in the 1960s and Switzerland in the 1970s, and extrapolating from research in other areas, Netting concludes that industrialized agriculture is not destined to replace (peasant) family farming everywhere. He treats households as work groups, with their members motivated to apply their knowledge and skills to the range of tasks required in localized agrarian social formations in ways that are efficient and environmentally sound. He documents their inputs through time allocation and their outputs in products for autoconsumption and the market. Netting's description of sustainable cultivation practices of the Kofyar of Nigeria, with hand tools and the inclusion of adults and children in the household division of labor, testifies to the possibilities for maintaining integration, security, and fulfillment in domestic farming in contrast to the fragmentation, insecurity, and alienation of agricultural wage labor. He finds similar work patterns in Swiss dairy farming families (cf Minge-Kalman in Applebaum, 1984) and contrasts these two ethnographic cases with the People's Republic of China, where collectivization countered venerable inequalities and vulnerabilities of the prior agrarian system, but where the regime eventually permitted greater household autonomy to reemerge.

From the Agricultural to the Industrial Revolution. Ethnographic studies of subsistence practices have necessarily taken mixed economic activities, also including fishing and herding, into account. Expanding networks of production and exchange have generated hybrid forms of work and multiple livelihoods, although degrees of self-sufficiency persist at the household and community levels. Economic downturns result in reversion to former practices, such as household gardening and inter-household barter, in situations characterized by exclusion or retreat from outside employment. Short-term and long-term economic and political reversals reinforce the significance of Netting's research on variable and incomplete transitions to large-scale, industrialized food production. Transitions from crafts production to technologically more advanced manufacturing are similarly incomplete.

Manufacturing

Manufacturing refers to the work of making things, whether with simple tools by hand (literally) or with heavy machinery or fully automated production systems. In the remote past, artisan roles developed through part-time or full-time specialization. Through the industrial revolution, artisan work was largely, although never entirely, replaced by the 'work' of machines. Anthropologists have studied a vast array of low-technology industries that persisted in some places such as Bolivia where large-scale manufacturing had not been established (Buechler and Buechler, 1992). Already in the early twentieth century, however, research in factories set the stage for new directions in the anthropology of work.

Workforce Organization in a Massachusetts Shoe Factory. Having first carried out ethnographic fieldwork under Radcliffe-Brown's guidance in Australia, W. Lloyd Warner was attuned to the way human behavior, including work, is structured according to status and role relations. Turning to research in the USA, he played a peripheral part in one of the pioneering experiments in applied industrial ethnography in the late 1920s. This was the flawed Hawthorne Project at the Western Electric plant in Cicero, Illinois, an attempt to apply the principles of Frederick Winslow Taylor to establish scientific labor control protocols. Warner contributed to an implicitly Fordist finding: the productivity of factory workers depended as much on morale as on rational organization of the assembly line. Warner went on to pursue his broader goal of developing anthropological concepts and methods relevant to the theoretical and practical problems posed by modern communities in urban-industrial settings. Newburyport, Massachusetts, was chosen for the renowned 'Yankee City' study he directed in the 1930s and 1940s. One resulting publication analyzes the composition and performance of the workforce in a shoe factory (Warner and Low, 1947). It traces this industry's long history, showing how job categories reflected divisions of gender, ethnicity, and national origin in the community at large. This enhanced the solidarity of immediate work groups but inhibited development of a shared working-class identity. The adversity of the Great Depression of the 1930s fostered worker solidarity, mobilized through a labor union in the 'natural history' of a strike. Marietta Baba (2009, cf Gamst in Gamst, 1995) attributes key innovations in the anthropological study of work to Warner, establishing protocols for the organizational research that came to the forefront in the closing decades of the twentieth century.

From Handicrafts to Heavy Industry and Beyond. Scattered through classic ethnographies – exemplified in the accounts by Boas, Malinowski, and Lee – are descriptions and analyses of the materials, processes, and arrangements of work involved in the making of tools and other objects. In subsistence-oriented societies, manufacturing was usually part of the mix of tasks performed in most if not all households, although some raw materials or finished products may have been obtained through exchange networks. Long-term industrialization and urbanization normalized full-time occupational specialization, and the factory worker became an iconic labor figure (Mollona et al., 2009). Much research has addressed technological and organizational changes in forms and conditions of industrial work, both where the human role persists, as in *maquiladora* assembly processes, and in more automated plants, where robots carry out tasks previously done by humans. Where manufacturing by hand has been revalorized in industries such as ethnic and tourist arts, anthropologists turn to new methodological and explanatory frameworks to accommodate its changing circumstances and meanings.

Coalescence of Anthropologies of Work

The preceding survey attests to the prominence of work as a persisting theme in anthropological research since the inception of the discipline, albeit more self-consciously and overtly for some scholars than others. When the *anthropology of work* emerged in the 1970s, the first programmatic statements embraced a comprehensive concern with work, conceptualized, and studied as broadly as possible. Anthropological investigations have ranged from direct subsistence practices through the gamut of other livelihoods, while also exploring the equivocal and previously neglected transitional areas between work and nonwork. These developments reflect reorientations in anthropology as a whole and its constituent subdisciplines. The authors of the case studies reviewed below have benefitted from participation in a collaborative cohort of practitioners investigating ever more detailed and kaleidoscopically shifting patterns in the world of work.

From Ethnography to Ethnology

By the late 1970s, anthropologists were making their shared interests in work more explicit. This newly recognized specialty was demarcated in publications generated from a groundbreaking symposium sponsored by the Association of Social Anthropologists in England (Wallman, 1979), sessions organized by the Society for the Anthropology of Work at meetings of the American Anthropological Association in the USA (e.g., Gamst, 1995; Nash, 1998), and a research group formed in Germany (Spittler, 2008). Along with theoretical and topical developments, methodological advances have supported more systematic comparative studies (e.g., the bioenergetic and time-allocation research previously mentioned). The emergence of the anthropology of work coincided with – and was stimulated by – the neoliberal turn in global political economy. Labor issues raised by deregulation, privatization, flexibility, and other attributes of *structural adjustment* presented ethnographic researchers with new interpretive and explanatory challenges (Nash in Nash, 1998; Collins, 2003; Ferguson in Mollona et al., 2009).

Since 1980, articles, reviews, and visual accounts have been disseminated through the *Anthropology of Work Review*, the journal of the Society for the Anthropology of Work, as well as other journals in many countries. Two of the leading publishers of books concerning the anthropology of work have been the State University of New York Press (formerly through its 'SUNY Series on the Anthropology of Work') and Cornell University Press. Given the limitations placed on references cited here, several are edited collections of articles that include interdisciplinary contributions and excerpts from exemplary monographs. This sampling highlights the theoretical development and ethnographic diversification of the anthropology of work, allowing for reference to only a few examples of the most recent scholarship. Readers interested in the themes explored here should track them in articles and the book review sections in the major journals.

Contesting the Boundaries of Work

Descriptions and analyses of work sites and situations, processes, and relations transcend the conceptual limitations of earlier models in anthropology and conventional assumptions in society at large. Ethnographic accounts published through the mid-twentieth century typically recorded a substantial residue of knowledge, beliefs, and practices in relatively stable

settings. From that period onward, cultural flux became the norm. These trends are particularly salient in reassessments of the development of women's work (Leacock et al., 1986).

Recognition of the mobility, subjectivity, and agency of workers responding to (or initiating) disruptions of long-established routines has led to reconsiderations of earlier scholarship. The so-called 'Bushman myth' controversy concerning the relevance of mid-twentieth-century food collectors' way of life for understanding early humans already has been mentioned. Nevertheless, critiques of our predecessors for writing in a timeless *ethnographic present* may attribute to them greater naïveté or bias than warranted. The shift of emphasis from continuity to change in anthropological research does not mean that preexisting configurations of skills, attitudes, and customs (*habitus*) necessarily become obsolete or irrelevant to ongoing survival strategies (Gamst on 'the web of rules' in Gamst, 1995).

June Nash's *We Eat the Mines and the Mines Eat Us: Dependency and Exploitation in the Bolivian Tin Mines* (excerpted in both Applebaum, 1984, and Mollona et al., 2009) demonstrates the resilience of Andean beliefs and practices in combination with Western religious and political ideologies. For example, to fortify themselves to withstand the rigors and danger of their work underground, tin miners both make offerings of coca to appease the syncretized 'devil' spirit (El Tío, or uncle) who holds sway over the underworld, including the mines, and chew the leaves as a mild stimulant. Leadership in protests for better working conditions was largely left to women, accustomed to the public work of managing community matters. Such examples of ethnic solidarity help explain how in 2006, an indigenous labor organizer from the federation of coca cultivator *sindicatos* could rise to become president of Bolivia, where neofeudal labor relations had persisted through the mid-twentieth century.

Beyond the ostensibly seamless blend of work and other activities in the natural economies of the imagined past, the conceptual and empirical boundaries of work have been effaced in at least three ways. A growing body of research addresses *unacknowledged work* supporting the lives of individuals and groups, spilling over from times and places designated by employment or applied to the quest for livelihoods lost or never secured. Under unstable economic conditions, *work in flux* has become the new norm, manifest through displacement, mobility, and improvisation. Anthropologists have become acutely aware of the *fuzzy boundaries of work* as it blends into a wide array of activities that support everyday life, political actions, aesthetic expressions, and leisure pastimes.

Diverse activities merge when workers create militant movements not only to claim material benefits as rights, but also to affirm identities as agents of their own destinies through art and other aesthetic expressions (Calagioni et al., 1992). This *affective* dimension of work has increasingly received attention, notably in Aihwa Ong's research on spirit possession as a response to women's factory work discipline in Malaysia and Carla Freeman's study of lifestyle enhancements, including professional attire, as a motivation for women's employment as highly regimented data entry technicians in Barbados (both in Mollona et al., 2009). The following topics illustrate other ways in which the boundaries of work are breached, both in lived experience and in ethnographic analysis.

Work without wages. From a cultural evolutionary perspective, paid employment emerged after millennia of diverse forms of work not formally distinguished from – on the contrary, integrated with – other activities and institutions. The legacy of slavery has been studied ethnohistorically and ethnographically, for instance, in the cases of the vestiges of colonial relations in the underpaid work of household domestics in sub-Saharan Africa (Hansen, 1989) and the field labor of Jamaicans in the ethnically stratified workforce on banana plantations in the Caribbean area (Bourgois, 1989). The historical emergence of the sector recognized as the *economy*, eventually entailing the commoditization of labor all over the world, left housework and others kinds of unpaid work as a problematic residual category (Wadel in Wallman, 1979). One collection of case studies by anthropologists and sociologists distinguishes labor for one's own domestic group and self-employment as two kinds of work not usually remunerated with wages (Collins and Giminez, 1990). Unpaid internships have become part of the neoliberal career path, although more traditional apprenticeships still can be found (Coy, 1989; Buechler and Buechler, 1992). Much unpaid work also remains hidden in the realm of consumption. Shifts to 'self-service' in retail sales can be seen as increases in involuntary unwaged work. From pumping one's own gas to scanning groceries and shopping from home, tasks associated with consumption have displaced many job categories (only partially replaced by supporting occupations to handle sales by phone or online).

Global Factories and International Labor Migration. The launching of the neoliberal era scrambled workforce designations, leading to unprecedented intersections of class, ethnicity, nationality, age, and especially gender. An early collection of case studies by Frances Rothstein and Michael Blim (1992) compares and contrasts localized manifestations of the 'global factory' in Mexico, China, India, Italy, Spain, the UK, Egypt, South Africa, the USA, and Puerto Rico. One trend has been the establishment of factories, often assembly plants in designated export-processing zones, in former colonies and Third World nations. A groundbreaking set of case studies collected by June Nash and María Patricia Fernández-Kelly (1983), with several featuring the roles of women in the electronics and apparel industries, focuses on workforce inequalities resulting from freer global flows of capital and labor. With the rise of transnational manufacturers powerful enough to resist regulation by overseas governments, a key factor in this shift of production away from metropolitan centers (runaway shops) has been the availability of cheaper and less-resistant labor. In the USA, in particular, the corresponding factory closings and the resulting unemployment – or the threat of factory closings – have been studied ethnographically (Nash in Gamst, 1995; Collins, 2003). Along with seasonal farm work, immigrants have occupied the onerous, low-paying niches that remain in manufacturing and processing (such as meat-packing) plants (Lamphere et al., 1994, Griffith, 2006).

Learning from Silicon Valley. The name 'Silicon Valley' evokes the rise of informatics, high-tech frontiers, and settings that foster creativity and productivity. New formulations of work regimes in the San Francisco Bay Area – emerging with the development and marketing of the first personal computers in the 1970s – have been replicated in other parts of the world. The emphasis on 'knowledge work,' including development

and management of highly automated manufacturing processes, supersedes production models originally developed for heavy industry. J.A. English-Lueck's *Cultures@SiliconValley* (2002) portrays lives and lifestyles built around work that spills over from cubicles and labs to eating and recreational areas and, with much of the interaction online, into homes as well. Research in Silicon Valley has contributed new insights and focused not only on elite knowledge workers and their families, many of whom are Asian immigrants, but also on other occupational niches. The ethic of raising the quality of work by eliminating rigid protocols and allowing for creativity is pursued in a study of photocopy machine service workers by Julian Orr (1996). Developing the concept of *work practice*, he explains how technicians repair the machines by triangulating symptoms of malfunction, statements of clients, and the maze of standardized procedures. They share a subculture of discourse-based expertise not recognized in their formal job descriptions. Christian Zlolniski's (2006) research on Mexican immigrants in this high-tech zone focuses on subcontracted janitors but also looks at workers in the informal sector: street vendors, care takers, and even providers of professional services (e.g., dentistry). It includes the work of social activism – political struggles for union recognition, the provision of public services, and legal residency – at the lowest stratum of this famously affluent regional economy.

Workscapes. David Hakken, in *The Knowledge Landscapes of Cyberspace* (2003), envisions possibilities for 'resocializing' work through automated information technology. He calls for 'ethnographic knowledgescaping' as a way of studying how people in principle can work together without physical proximity or hierarchies of control. We can extend these ideas beyond informatics to the increasing fluidity of low-tech as well as high-tech work as people adapt their skill sets and work settings to transcend (or not) the disappearance of countless occupational niches and the emergence of new ones. Thus, while ethnographers still conduct fieldwork on farms, in factories, in offices, and at other relatively self-contained sites, deterritorialized modes of research – whether by following workers from place to place or tracking their activities in cyberspace – are increasingly coming to define the anthropology of work. A few more examples of new occupations – or old ones studied in innovative ways – are weavers and woodcarvers in Mexico, offshore call-center workers in India, second-hand clothing merchants in Zambia, tourism workers in Barbados, Chinese workers in a Korean factory in China, open-source software 'hackers' in California, Indian migrant laborers in Bahrain, child laborers in Brazil, Filipina domestic workers in Hong Kong, drug dealers and sex workers in New York, therapists for victims of workplace harassment in Italy, the work of young men looking for work in Ethiopia, and foreign news correspondents around the world.

Reflexivity and the Work of Anthropology

With the acceleration and intensification of globalization at the time the anthropology of work coalesced as an intentional research specialization, concern about the history of anthropology was also growing. This has encouraged a critical perspective on the work of anthropologists themselves (Fabian, 1991). Participation in colonial administration and other government programs has generated much controversy over the years. The ethical and scholarly issues that arose over 'embedding' anthropologists in military units in Iraq and Afghanistan are an extreme example of debates about entanglement in armed conflict that have divided the discipline in the USA since the Vietnam War but go back to the formative stages of field research under the auspices of nineteenth-century imperial states. Another area of debate has been the engagement of anthropologists in the proliferation of socioeconomic 'development' programs, with research ostensibly carried out under the premises of value-free science.

Contemporary anthropologists continue the legacy of fieldwork in marginal or peripheral settings from the bottom-up perspective of people whose working lives have been increasingly uprooted and displaced (Nash, 1998). With a shift to over half of professional anthropologists working outside of academia and other traditional venues such as museums, it has become less uncommon to be hired by the constituencies traditionally studied, carrying out research, for instance, on behalf of indigenous groups or labor unions (Field and Fox, 2007; Durrenberger and Reichart, 2010). Now anthropologists are likely to conduct research in urban neighborhoods and institutional settings – medical facilities, schools, offices, restaurants or bars, or more diffuse workspaces – rather than in relatively discrete communities. Anthropologists are also more likely to study groups with which they themselves identify (autoethnography). Whatever the setting and focus, they enter the field less as relatively powerful strangers able to act on their own volition than as guests who must justify their presence to the people they presume to study (Gellner and Hirsch, 2001).

The adoption of practice theory to assess the relationship between structure and the agency of anthropologists in situations in which investigations occur has also drawn attention to research ethics, including dissemination and use of findings. To the extent that such reflexivity transcends narrow or simplistic research strategies, practitioners of the anthropology of work can be characterized more by their attitude or angle of approach than by a clearly demarcated set of principles and methods that constitute an institutionalized subdiscipline. A central concern with work leads in many directions related to elements of social life encountered in its evolutionary roots, institutional manifestations, political economy, and expressions of cultural identity.

Abstract

The article brings together two themes. First, it discusses the history of the concept of work, from the philosophers of Antiquity and the Judeo–Christian tradition to modern Western thought. Second, the article concentrates on the history of work as practice. In doing so, three perspectives are employed, which predominate in the historiography of work from its very beginning until present: work as production and application of technology, work as economic activity, and work as culture. Finally, the article discusses the relation between work and gender as a field in which concepts and practices of work are closely interrelated.

The concept of work designates certain human activities; however, those activities that are considered to be work and those that are not, vary among different cultures and epochs. Each historical society has its own definition of work, and a variety of different conceptions are juxtaposed to one another within each society. How work is defined is closely associated with the value placed on it, and this in turn is connected with workers' positions in society. The history of work must therefore bring together two themes: the history of the meaning of work and the history of work as a practice. The relation between gender and work cuts across these two themes and shows how strongly they are connected.

History of the Concept of Work

The state of research on the history of the concept of work and the meaning of work suffers from three shortcomings. First, it is based upon the reflections of the intellectual elite. The ways in which other social groups – above all, the workers themselves – understood and evaluated work have not left much of a trace in historical source material, nor has much research been done on this tissue. The history of the concept of work is a history of ideas, and – in very few approaches to this field – a history of mentalities as well (Le Goff, 1980). Second, research has tended to ascribe a unitary – or, at least, a predominant – concept of work to the respective historical society under investigation. Contradictory or conflicting attitudes have been almost neglected. Third, the history of the concept of work has remained Eurocentric. Despite the pronounced interest in the work ethic of non-European cultures and religions that was already evident in the work of Max Weber, and in spite of the growing interest in global history, a systematic intercultural comparison remains a desideratum (Godelier, 1980).

Concepts of Work in Preindustrial Societies

The history of the concept of work in Western historiography begins as a rule with the great philosophers of Greek Antiquity (Aristotle, Plato) (Conze, 1972). They employed the term work (*ponos*, *poiesis*) to designate work done manually, and described thereby activities that required physical exertion and strength, that presupposed the use of tools, and the aim of which was to turn out a particular product. The meanings that coalesced to define the word *ponos* included labor, toil, hardship, and suffering. This concept of work had a parallel in the Indo-Germanic languages, which as a rule contain several terms for work and working: *labor* and *opus* in Latin, *travailler* and *ouvrier* in French, *labor* and *work* in English. The first word stem means great effort, travail, and affliction, activities dictated by necessity or constraint. The second word stem refers to the results of this effort – the attainment of a certain goal, the creation of a product.

Most historians agree that philosophical and political thought in Antiquity was characterized by contempt for work. Work was an evil, the activity of slaves, while the élite engaged in art, philosophy, and politics. The connection between abhorrence for manual labor and slavery is confirmed by the contrast provided by non-European cultures. Slave labor did not play an important role in the historical societies of East Asia, in whose great religious-philosophical systems – foremost among them Buddhism and Confucianism – work (the fieldwork of peasants and the handiwork of artisans) had a positive connotation. But European Antiquity was also characterized by contradictory attitudes toward work. Critical schools of thinking such as the Cynics esteemed physical and mental labor and contrasted them to idleness, which they regarded as a vice. In ancient Rome as well, particularly during the Republic, peasant farm work performed by free men was not seen in a totally negative light.

In the Judeo-Christian tradition, the ambivalence of the concept of work is expressed with particular clarity. In the Old Testament, God himself appears as a worker, and man was originally meant to care for God's creation. "And the Lord God took the man, and put him into the garden of Eden to dress it and to keep it" (Genesis 2:15). However, with man's fall from grace, work became penance and punishment: "In the sweat of thy face shalt thou eat bread" (Genesis 3:19). The New Testament carried forth this ambivalence. Christian writings of the Middle Ages constitute an "ideological arsenal containing weapons for the defence of every position, in favour both of labour and nonlabour … ranging from … contempt and condemnation to a tendency to respectful evaluation" (Le Goff, 1980: p. 77). From the tenth century on, a new trifunctional or tripartite social schema took hold; it divided society into 'priests' (*oratores*), 'warriors' (*bellatores*), and 'workers' (*laboratores*). This model assigned all working people to the lowest level of the social hierarchy, but nevertheless made them an

indispensable segment of society. The Reformation strengthened the tendencies to enhance the status of work. Luther and Calvin understood work as serving God. The work that each Christian performed was considered a 'calling' or a 'divine calling,' and thus assumed a quasi-religious character. The adherents of certain Protestant denominations – above all, the Puritans – regarded success they achieved in their work as confirmation that they numbered among God's elect. Since the publication of Max Weber's study (1904/1905), it is generally accepted that the higher valuation of work during the Reformation legitimated and promoted the spread of a bourgeois work ethic, even if it has important roots in medieval thought.

Concepts of Work in Modern Western Society

In early modern Europe, work was redefined in two respects. The first definition exhibits anthropological traits. Work came to appear as active human intervention in nature for the purpose of assuring the ongoing existence of the human species. At the same time, work appeared to be a social process based upon collaboration among human beings. This new idea of work played a central role in Enlightenment philosophy and the writing of cultural history done during this period. Man was seen as ruling over nature; division of labor and cooperation as the foundation of human socialization; and increasing domination of nature and further division of labor as the very epitome of social progress. Tools were considered the basis upon which human dominion over nature rested. Man thus appeared to be the 'tool-making animal,' as Benjamin Franklin put it. In the nineteenth century, Karl Marx and other thinkers of the early Industrial Age carried on this intellectual tradition. In his classic formulations in Volume I of *Das Kapital*, Marx described this dual character of work: "Labor is, in the first place, a process in which both man and Nature participate, and in which man of his own accord starts, regulates and controls the material re-actions between himself and Nature …. By thus acting on the external world and changing it, he at the same time changes his own nature" (Marx, 1867(1968): p. 192).

The second redefinition originated in the seventeenth century in the field of political economy, which linked the concept of work with the idea of value. Work was defined as an activity that created value, and value-producing activities were considered to be all those that were for pay or that generated income. This led to equating work with paid labor. In industrial capitalism, paid labor became the very epitome of work.

These new definitions were associated with the greatly enhanced status of work. "The modern age has carried with it a theoretical glorification of labor and has resulted in a factual transformation of the whole society into a laboring society" (Arendt, 1958: p. 4). Paid labor became the basis of self-esteem, social recognition, and political participation – in short, the admission ticket to civil society. However, attitudes toward work were ambivalent in modern society as well. The classic works of political economy of the eighteenth and nineteenth centuries, beginning with Adam Smith, feared the brutalizing and stultifying effects of extreme division of labor and repetitive mass production. For Marx, work in capitalism was exploitation and alienation; his communist utopia vacillated between self-realization by means of work and liberation from it. These ambivalences were expressed in increasingly multifaceted views of work. The esteem accorded to work referred to a specified type of work in contrast to its polar opposite, which was assessed negatively; mental verses physical work, planning and supervision verses actually performing tasks, skilled verses unskilled work, a steady job verses 'casual labor,' 'proper' work verses housework. A complex hierarchy of work is an essential component of the modern concept of work.

Work as Practice

Which activities were taken into consideration by scholars compiling the history of work as practice is closely connected to the development of the concept of work. Three perspectives emerge in the historiography of work: work as production and application of technology; work as economic activity; and work as culture.

Work as Production

The conception of work as dominion over nature that had emerged in the seventeenth century began to exert an influence on the history of work in the nineteenth century. Benjamin Franklin's characterization of man as the 'tool-making animal' was cited approvingly by Marx. Tools, or, in more general terminology, instruments of labor, were for Marx, fundamental to the periodization of history and a yardstick of human progress: "It is not the articles made, but how they are made and by what instruments, that enables us to distinguish different economic epochs" (Marx, 1867(1968): p. 194). Proceeding on this basis, Marxian historians and archeologists developed a world historical perspective on work that focused on two (or three) 'revolutions in the forces of production' (Childe, 1936; Bernal, 1954).

The first of these was called the Neolithic Revolution. Its point of origin was the Near East (Southern Anatolia, Mesopotamia, the Jordan Valley) and between about 8000 BC and 3000 BC it spread over large portions of South, East, and Southeast Asia, North Africa, Europe, and Central America. The essence of this revolution was the transition to agriculture and animal husbandry as the most important basis of human existence, and in the emergence of agrarian (farming) societies. According to this view, this was the beginning of goal-oriented human intervention in nature and was thus, in an alternate formulation, the beginning of work. "Early men did not work at all in the true sense … real work, steady work, labor for one's livelihood, came into being when agriculture was invented" (Williams, 1976: p. 335).

The second great revolution in the forces of production was, from this perspective, the Industrial Revolution, which began during the second half of the eighteenth century in Western Europe and encompassed large parts of the world over the course of the nineteenth and twentieth centuries. Now, the tools employed in performing work were no longer operated manually by the human hand, but rather by a machine that was driven by artificially produced energy. Thus, production became independent of the skillfulness, endurance, and physical strength of human beings. In capitalist fantasies, as in Andrew Ure's *Philosophy of Manufacturers*, 1835(1969), machinery even functioned as the most perfect means to

control and to discipline the workforce, as the final victory over the obstinate spirit of the workers. Factory, mass production, and conveyor belt became the symbols of work in industrial society.

The increasingly important role played by microelectronics and the computer in industrial production since the 1960s appeared, in this perspective, as the third great revolution in the history of work. Now, human beings withdrew from the process of controlling production and turned over mental activities as well to a machine, the computer. Automation, or flexible communication between humans and computers – a 'man–machine dialogue' – seems now to be the defining characteristic of a new world of work. The amount of human labor necessary for direct production is on the decline. The production process is increasingly becoming the activity of a 'collective worker' (Marx), in which technology and science play an important role.

This 'grand narrative' was subjected to critique and developed further by scholars working in the history of technology, a field that became over the course of the twentieth century an independent academic subdiscipline (cf 62117). Its early practitioners were engineers and technicians with their own narrow understanding of technology, who were not interested in human agency, but in the interaction of material objects. As early as the 1930s (Bloch, 1967), however, economic, social, and cultural historians were beginning to get involved in this field, and making the effort to conceive of technology as an integral part of society, and thus to conceive of work in an all-encompassing sense. In contrast to Marxist 'history of the forces of production,' they emphasized the numerous small technical innovations made in all historical epochs. An evolutionary perspective predominated in the history of technology. What the two approaches have in common is the tendency to represent the history of work as developing along a path rising in linear fashion, and as the history of progress.

Work as Economic Activity

At around 1900, with the newly awakened interest in economic and cultural history, there was also increased demand for a history of work, which then proceeded to emerge as a not-very-clearly delimited subdivision of general economic and social history of various different cultures and epochs. Since then, the history of work as an economic activity has been focusing on work as wage labor; on working hours, wages, and working conditions; and on the history of the modern work ethic and work discipline.

Wage labor was widespread in many preindustrial societies. In Europe, it took on increased significance from the late Middle Ages. Over the course of the Early Modern Period, the population became increasingly dependent upon wage labor. In the economically most highly developed regions of Europe, the 'proletarization' of the populace was a precondition and not a consequence of the Industrial Revolution. In the industrialization process of the nineteenth century, wage labor in its 'pure' form ultimately established itself as the predominant type of labor relationship. Among the features that typically characterized it were the standardization and regulation of work, including a high intensity of labor, a regular working rhythm, and a highly pronounced working discipline; a high degree of specialization of work along occupational lines; a clear demarcation of time spent at work and time off (over the course of a day, a week, a year, and a lifetime); the separation of the workplace from home; and a complex system of institutional and legal regulation.

The development of wage labor, however, was not a linear process. Recent research has shown that diversity of labor relationships was characteristic of the period from the late Middle Ages to the eighteenth century. A growing number of men and women earned their daily bread from a combination of agriculture, crafts and trades, and commercial activities, and by combining self-employment with wage labor. A high degree of flexibility and increased readiness to undertake labor migration were preconditions called for by this mixed economy. Flexibility, however, was not only a voluntary practice, but was enforced by the instability of the economy, by necessity and misery. The French historian Fernand Braudel suggested that commercial capital and industrial capital, small workshops and large-scale enterprises, rural home industry, and centralized manufacturing during this period should not be regarded as sequential phenomena, but rather as a pool of possibilities, as coexisting labor relationships and modes of production, among which men and women could choose and switch.

An ongoing point of discussion is the question of why men and women of the Early Modern Period increased the intensity of their work. Was this attributable to the exigencies of hardship in an increasingly polarized or proletarianized society, as mercantilist economists of the seventeenth century presumed? Was it the capitalist entrepreneurs who used shop regulations and penalties to turn up the pressure upon their employees (Thompson, 1967(1993))? Was the transformation of the world of work simply a part of a general disciplining process – including workhouses, prisons, and schools – to which men and women were forced to submit (Foucault), or to which they – as part of the process of civilization (Elias) – subjected themselves? Or was it the transformation of material culture – namely, the brave new world of consumer goods that expanded so rapidly in the Early Modern Period – that made working harder acceptable, or even desirable? Are the beginnings of consumer society thus also the historical roots of the laboring society (de Vries, 1994) (see Consumption, History of)? Which role was played by the changing perception of time, by which – from the fourteenth century on – Europeans began to adapt to the abstract rhythm of mechanical clocks? No matter how these questions are answered, it is clear that the role of the Industrial Revolution and mechanized factory labor as factors giving rise to the modern world of work have been devalued, whereas more emphasis is now placed on the long history of capitalism.

The industrialization process, too, became a field of revisionism. As it is conceived now, it was not represented by the factory alone; handicrafts, skilled work done by hand, and small-scale enterprises continued to play a key role (Sabel and Zeitlin, 1997; Samuel, 1977). The diverse branches of the service sector, such as transportation and shipping, retailing, education, entertainment, and the widely varied world of office work would very soon be employing more men and women than the manufacturing sector. In most industrial states, a majority of the workforce has never been employed in the secondary (industrial) sector. And ultimately, factory work has

proved to be more varied than it had long appeared to outside observers.

The concentration of research on the 'ideal type' of paid labor in modern society has caused too little attention to be paid to forms of labor that deviate from that model. This applies, for instance, to various forms of unfree or forced labor. In European history since the Middle Ages, slave labor has not been widespread, but as a basis of the Atlantic economic system from the sixteenth to the nineteenth century, it was indeed an essential component in the emergence of industrial capitalism. However, forced labor was widespread in the totalitarian political systems of the twentieth century. Seen from a global perspective, 'free' and 'pure' wage labor has (still?) not become the predominant form of work. Today, both agriculture as well as a combination of different activities and forms of work – as was characteristic of European history during the Early Modern Period – provides work and a living to a majority of the world's population.

Work as Culture

Since the 1980s, a new way of looking at the history of work has become widely accepted. A growing number of historians consider work as culture. As far as the concrete practice of research is concerned, this means a microhistorical perspective focusing on the workplace itself. Particular attention has been paid to two types of workplaces: first, the small workshops of artisans in the Early Modern Period and in the nineteenth century, that represent, on one hand, 'traditional' work, and, on the other hand, their increasing integration into capitalist relationships of production (Kaplan and Koepp, 1986); and secondly, the factories of industrial enterprises of the late nineteenth and the early twentieth centuries, as symbols of the modern industrial world of work (Lüdtke, 1993). The chief focus of these microhistorical studies is upon day-to-day working processes themselves and on social relationships in the workplace. They show the enormous diversity of practical labor and thus constitute a much-needed corrective to the generalizations yielded by the macrohistorical perspective. Scholars investigating the cultural history of work have also attempted to reconstruct the meaning of work for, 'common, everyday people' by using 'ego documents' such as autobiographies and diaries; iconographic and pictorial sources; and oral history interviews (cf Passerini, 1982).

There has also been great interest in the symbolic and ritual forms in which solidarities and conflicts are carried out and resolved on the workplace (cf Darnton, 1984). In investigating these phenomena, the microhistorical perspective also extends beyond the immediate confines of the workplace. Work gives rise to social relationships that retain their significance beyond the workplace, the term 'world of work' is used to connote this expanded meaning.

Often, work's significance becomes clearly evident only when it is absent. The implementation of the working norms of industrial capitalism also led to a redefinition of being out of work. Between 1880 and 1910, a new term describing involuntarily not working, became widespread: unemployment (*Arbeitslosigkeit*, *chômage*) (Topalov, 1994). The first microanalysis of work and unemployment that became one of the classics of twentieth-century social science is the study *Die Arbeitslosen von Marienthal*. In this small Austrian factory town in 1932, the textile mill that dominated the village's economic life shut down, so that practically the entire population was thrown out of work overnight. As a result, the rhythms of everyday life became slower and slower, and the unemployed were able to summon less and less energy for activities that they had previously pursued enthusiastically during their free time (Jahoda et al., 1933).

This draws attention to the fact that leisure is, on the one hand, the antithesis of labor, although on the other hand, it is also part and parcel of the world of work. In preindustrial societies, there was no strict dividing line between working and not working. The peasants of the Occitanian village Montaillou, who in about 1300 were interrogated by envoys of the inquisition about their way of life, interrupted their labors at the slightest opportunity – to chat with neighbors, to hang around the village square, to have some fun playing a game (LeRoy Ladurie, 1975). It was only Industrial Society that drew a clear distinction between working and not working, thereby changing the character of not only the world of work but of leisure as well. The concept of leisure refers less and less to merely not working and rather more to an ensemble of activities pursued by specific classes at certain times, such as games, sports, watching TV, and going to bars or symphony concerts. In this sense, leisure seems to some historians to be a cultural practice that was not 'invented' until the Early Modern Period (Burke, 1995).

Work and Gender

The relation between work and gender is a field of scholarship in which the reciprocities between the concept and practice of work, between work as economic activity and as culture, can be seen with particular clarity. Early studies of women's work conducted up into the 1970s almost exclusively treated gainful employment on the part of the women. Initial interest was focused upon factory labor, and then increasingly on 'specifically feminine' occupations like maid, governess, midwife, teacher, secretary, and salesgirl. The aim of this research was to reintegrate women into the male-defined world of paid labor. Beginning in the 1970s, feminist historians increasingly criticized the prevailing modern concept of work. Housework became the subject of theoretical discussions and of empirical investigations. Increasingly, studies on the history of women's work focused both on gainful employment and domestic activities (Tilly and Scott, 1978; Simonton, 1998).

The issue of the division of labor between the sexes has become a much-favored field of interdisciplinary research. Anthropologists, historians, and sociologists have shed a great deal of light on the variability of the division of labor. One and the same activity can be a typical man's job in one culture and woman's work in another. Which work is done by men and women does not depend on the 'nature' of their respective sex, but upon socially constructed gender roles. Recent theoretical approaches oppose biological or 'biosocial' as well as cultural determinism. Emphasis is in the variety of options taken in the sexual division of labor and the contesting definition and redefinition of norms.

In European history of the late Middle Ages and the Early Modern Period, the economic significance and the symbolic meaning of the respective activities assumed decisive explanatory power. One research approach emphasizes the exclusion of women from market-oriented activities in agriculture, crafts, and trades. Work that promised to yield profits, was learned and practiced according to formalized rules, coalesced into formalized occupations, and had organized politically along occupational lines became the domain of men. Early 'classical' studies of women's work and some recent research proceed under the assumption that up to the beginning of the modern period women also took part in artisanal market production and were organized in guilds – either in exclusive women's guilds or mixed guilds (Wiesner, 1989). According to this perspective, it was not until later that there occurred a gradual exclusion of women, be that as a consequence of 'male bonding,' the spread of capitalism, or the Industrial Revolution. Other historians have stressed the continuities of the gender-based division of labor since the twelfth century, which placed women in the domestic sphere or in low-skilled, low-status, and low-paying occupations (Bennett, 1988). Most historians emphasize the fluctuating boundaries between men's and women's work, which are continuously redefined and renegotiated (Honeyman and Goodman, 1998).

Another research approach emphasizes the cooperation between men and women. In this perspective, the 'working couple' formed the economic backbone of the agrarian and the artisanal economy (Pahl, 1984; Wunder, 1992). This can be seen even more clearly in the 'family economy' of the lower classes. Women played a central role in efforts to exploit and combine as many of the available income opportunities as possible. The 'industrious revolution' that preceded the industrial one in the view of many historians, was based on the cooperation of men and women in the family economy (de Vries, 1994). Conflict and cooperation are not necessarily antagonistic but rather complementary perspectives on the gender-specific division of labor in preindustrial Europe.

With respect to the nineteenth century, the focus of research has been on the 'male breadwinner model' and the emergence of 'separate spheres,' which made paid labor the exclusive domain of the male and, conversely, explained domesticity and care of children as being appropriate to the female nature (Janssens, 1998; Hausen, 1981). This was an effective model, even if there are diverging assessments of its effective range and the extent to which it actually did determine practice. Indeed, it was a short-lived model. The proportion of women pursuing paid labor began to climb again in the 1960s, including highly qualified professional work and lifelong careers. The history of the division of labor between the sexes shows that "the division of labor is an effect of the social hierarchy, not its cause" (Godelier, 1980: p. 170).

The feminist critique of the concept of work in modern society has considerably widened the boundaries of the history of work. Since generally applicable definitional criteria are not in sight, they have to be developed from case to case. "In this widest sense" the English historian Penelope J. Corfield wrote, "'work' is whatever people consider as work … the boundaries between 'work' and 'non-work' are in practice very often obscure" (Corfield and Keene, 1990: p. 208).

Work, Labor: History of the Concept

Bénédicte Zimmermann, Ecole des Hautes Etudes en Sciences Sociales, Paris, France

Abstract

Work refers as much to the content and the performing of an activity, to the production of economic goods and values in capitalist societies, as to the production of social identities and hierarchies. Since the late nineteenth century, capitalist societies have essentially been built on the two latter meanings, reducing work to labor, that is to abstract work that can be quantified and measured in time and money. The history of the concept is closely linked to the constitution of a social order on the basis of standards of class and nation in the framework of the welfare state, as well as to the production of its principles of intelligibility by the social sciences.

The concept of work has at least three different but complementary meanings in contemporary Western societies. As an action, it refers to the content and the performing of an activity; as a production of value, it is part of the organization of capitalist societies; finally, as a status, it constitutes a linchpin of social organization. Work, as the mainspring of economic activity, is also at the crux of the functioning of the political and social order. Affecting the slightest aspects of life in society, it can be viewed as a 'total social fact' (Mauss, 1966/1950). This pivotal position has made work a notion that has long been taken for granted as universal, to the detriment of its changing meaning in time and space. Neither has work always been a pillar of the social and political order in Occidental societies, nor does work similarly serve this function in any society. In Asian or African countries, the perception of work, its role in society and, therefore, the history of the concept took quite a different road (Kocka and Offe, 2000).

Yet its contemporary meaning in capitalist societies is the result of an eminently historical process, which made out of it a yardstick for economic and social organization. Although various meanings of the word 'work' existed in the nineteenth century (Cottereau, 1994), it is on the particularly restrictive concept of labor, in the sense of quantifiable productive activity, that Western capitalist societies have been built. The history of the reduction of the concept of work to that of labor, that is, to abstract work that can be measured in time and money, is also the history of the constitution of a social order based on wage labor in the framework of the welfare state. It is closely linked to the building of a collective order on the basis of standards of class and nation, as well as to the production of its principles of intelligibility by the social sciences.

Labor, conceptualized in political economy after Adam Smith under the angle of the production of value, became as a mediator between the individual and the collective, a focal point of sociological analysis. Hence, the transformations of productive activity and their consequences in industrial society have strongly contributed to shaping the development of the social sciences, but the descriptive as well as prescriptive discourse of the latter has also played an essential role since the early twentieth century in establishing the social sphere on the basis of work. The *Verein for Sozialpolitik* in Germany and the Fabian society in England provide cases in point for such an intertwining between social reform purposes and social sciences (Rueschemeyer and Skocpol, 1996).

The history of the concepts of work and labor will be examined from this angle of a dual process in which the social sciences and the societies they study mutually engender one another. Thus delimited, the history will not be a 'total' one, but situated in time and space, that is, focused on the question of the reduction of the concept of work to that of labor in capitalist European societies from the nineteenth century onward. At the turn of the twentieth century, this history overlaps with that of the statistic and legal codification of labor into social status, providing access to citizenship within the welfare state. Finally, since the 1980s, it turned into a reopening of the concept, closely tied to a reassessment of paradigms of action in European social sciences, after the dominant role played by functionalism and structuralism.

The Semantic Reduction of Work to Labor

Labor, more precisely wage labor, a dominant form in social-economic relationships in today's societies, has not always had this value as a standard. In the Middle Ages, when idleness was the privilege of the aristocracy, labor was synonymous with pain, poverty, and social devaluation. Without going back over the history of work (*see* Work, History of), it is important to underline the contradictory heritage that characterizes the notion in the nineteenth century. On the one hand, work was associated with the idea of alienation. This association finds its origins in the Greek conception of slavery, the function of which was to satisfy the vital needs of reproduction of the human species (Arendt, 1958). It was further developed by Marx's critique of wage labor, a modern form of alienation through work. But on the other hand, as Marx himself noted it, work is a source of individual accomplishment and self-expression. This alternative conception, fueling the Protestant ethic and its formalization of an occupation (*Beruf*) as a vocation (Weber, 2010/1920), as well as Hegel's conception of work as the essence of man (Hegel, 1977/1805), considerably fed the ideology of the welfare state. The tension between alienation and liberation was to mark the concept of labor in the long term and run through theoretical debates in the social sciences until today (Méda, 1996).

The Invention of Abstract Work

The contradiction between the anthropological conception of work as the essence of human existence and the reality of alienating labor provided the basis of the Marxist critique of the political economy (Marx, 1968/1867); a critique that marked a major turning point in the conceptualization of work (Noguera, 2011). Political economy produced an initial swing of the concept of work toward that of labor. This swing occurred in the context of liberalization of work, consecrating the idea of the market through the promulgation of a set of legal provisions abolishing hereditary dependency, establishing the free circulation of individuals, freedom of commerce, and free competition. On the theoretical level, Adam Smith's work (1776) consecrated labor as a value, as a source of national wealth, and saw freedom of work as the means to maximize this wealth. From Adam Smith to John Stuart Mill, British theorists of political economy made labor a product, a commodity sold according to the laws of supply and demand, on a market held to be the dominant form of regulation. Determined by the principles of economic liberalism, this conception makes out of work a commodity having an exchange value. According to the principle of individual freedom, each person was theoretically supposed to be able to sell this commodity as he or she wishes by way of freely agreed contracts. The contractual mediation made out of work a general and legal category. It meant the invention of abstract work, quantifiable and measurable in time and money: the invention of labor as a founding principle of capitalism (Biernacki, 1995).

Marx embraced this conceptualization of abstract work, but introduced two new elements. The first was labor power. Marx viewed labor as much from the perspective of the production of economic value as from the angle of the labor power (*Arbeitskraft*) required to achieve it. Doing so, he introduced a significant shift in the problematics of work. Work is no longer reduced to the mere economic dimension of producing and circulating goods, it is henceforth associated as well with the condition of the producer in a capitalist market system. The second contribution of the Marxist critique is the introduction of non-work, a notion previously absent from political economy (Marx, 1982: p. 208). Seen from the angle of the economic dependence of the worker, who can only meet his needs through the sale of his labor power, labor cannot be envisaged independently from non-work and its individual consequences. Marx thus contributed to a conceptualization of labor as dependent work, that is, seen from the producer's rather than the product side. This Marxist critique of political economy provided, in the second half of the nineteenth century, a fertile ground for the development of the social sciences. One of their contributions has been to objectify non-work by breaking it down into categories of social organization such as old age, disability, illness, and unemployment.

Wage Labor: A New Expression of Dependent Work

The concept of work used for this purpose of social objectivation meets the dual criteria of quantification and dependence. The reformist social sciences of the early twentieth century and the new categories they contributed to producing thus reinforced the process of dissociation between on the one hand work as a creative activity, characterized by the independence of the producer and the quality of the product, and on the other hand abstract work associated with dependence and quantity. This social differentiation grew more marked up until the 1960s, along with the spread of wage labor which was legally codified – by the means of labor contracts and labor legislation – and statistically codified, in the form of socio-professional categories, as a response to standardization and mass production in economic activity.

The concept of employment, at the heart of the legal codification of labor, is informed by a dual meaning: from a macroeconomic standpoint it means trading a given quantity of work for a given salary on the market; from the political and social standpoint, it means exchanging individual subordination – the worker's subordination to his employer – for security, the security offered by labor legislation and social protection. From this standpoint, employment is as much determined by the nature of economic activity as by the nature of the social relationships that regulate this activity. Employment can thus be defined as socialized labor, including, in response to the Marxist critique, protection for the producer. But this protection is highly variable geographically, reflecting the different avenues of building societies around the integrative virtues of work (Esping-Anderson, 1990). As Biernacki (1995) has shown in the case of England and Germany, the historical forms of objectivation of labor specific to each country – as a product for the English, as labor power for the Germans – affect the way in which the concept of labor is still operating nowadays in the production of the political and social order.

Labor and the Constitution of the Social Order

With the welfare-state, labor has become the nerve center of the social world. As participation in the common good, it was used at the end of the nineteenth century in the definition of a link that binds together individuals in the broadened framework of the nation-state. Consequently, it has been codified as a vector of individual belonging to the collective, insuring the group's cohesion.

The social sciences, as institutionalized at the turn of the twentieth century, played an essential role in this codification, indexing the social order on labor and defining labor's relationships as a matter of public concern (Durkheim, 1964/1893; Weber, 2010/1920). During the first half of the twentieth century, producing general categories aiming to organize the industrial society at the level of the nation-state was of major concern for most prominent social scientists. Stating scientific principles of homogenization and generalization ran parallel with the organization of society on a large scale, using labor as a fulcrum for standardization and social regulation within the framework of national institutions.

Labor as a Status

The close connection between work and social status is one of the main features of the concept of labor. This type of connection doubtless already existed in feudal societies and guild organizations, but its specificity since the late nineteenth

century lies in its relation to demands of social justice, political equality, and democracy. Labor has become the democratic means of access to social status and political integration, a function that for centuries was ensured by property and heredity (Castel, 1995). As a provider of income and the principle on which the redistribution of wealth is based, labor has become the central social relationship in capitalist societies. It contributes to determining social hierarchy and individuals' position within it, as well as shaping forms of citizenship and personal identities. Therefore lack of work, categorized as unemployment by the welfare state, does not only mean a loss of income likely to be compensated by social policies. Its consequences for individuals reach far beyond the shortening of economic resources. As shown by Jahoda, Lazarsfeld, and Zeisel in their ground-breaking study (2002/1933), unemployment causes a range of other disorders which bring to the fore the psychosocial functions of work. These "latent functions" (Jahoda, 1982), which become most relevant when one is unemployed, encompass collaboration with others, access to social interactions, constitution of social identity, as well as structuration of time and making sense of one's own life and role in society. The centrality of work in the constitution and organization of society, was not, however, a foregone conclusion even two centuries ago (Arendt, 1958). But it has become such a natural fact within welfare-based societies that it is today taken for granted (Zimmermann et al., 1999).

Labor, Class, and Nation

The socialization of work and non-work fulfills a double purpose in the political project of the welfare-based nation-state: providing security for wage workers through social protection and labor legislation and, thereby, consolidating the political legitimacy of the nation-state. This conjunction considerably increased the social value attached to paid and dependent work. The expression 'social security' suggests to what extent the socialization of non-work is as much a question of collective as of individual security. Collective, that is, social, security is based in the national welfare-state on the dichotomy between capital and wage labor, according to a scenario in which the social regulation of labor is thought of as a partner of economic regulation of the market and a basis for economic development. The encounter of the nation-state, economic organization, and labor institutions under the auspices of the welfare state thus appears as the fruit of a historical compromise between capital and labor. This compromise, at the basis of Fordism, is founded on the norm of full employment. From such a perspective, the social order can be seen as a collective order produced on the basis of wage labor and codified by a set of rights and duties attached to the salaried class (Castel, 1995).

The history of this collective order is, from 1890 to 1960, one of establishing a coherence between individual identities and economic and political practices on the basis of the principles of class and nation (Wagner, 1994). It is a movement of widespread standardization aiming to reduce uncertainty as well as the variety of possible actions and interpretations. Statistical and legal methods were the preferred instruments of this standardization and establishment of equivalences, going hand in hand with a dominance of the functionalist and structuralist paradigms within the social sciences. Through the institution of nomenclatures, statistics gave shape to a homogenous national body that can be observed and planned thanks to the presumed objectivity of figures. By granting social and political rights guaranteed by the state, legal codification stipulated individual belonging to this body. But during the two last decades of the twentieth century, these standardization principles have been put to the test by increasing demands of flexibility and the diversification of contractual status of workers, especially wage earners.

Transformations in Work and the Reconfiguration of the Social Sciences

At the turn of the twenty-first century, the quest for generality of the early twentieth century has been replaced by a concern for diversity. This holds true for economic and social life as well as for the social sciences. The issue has turned into producing new equivalencies between situations and persons, able to place increasingly individualizing practices into a collective order that guarantees equity. The requirement for flexibility, which spread from the financial markets and economic sphere to the whole political and social life, provides an exemplary illustration. Whereas flexibility is for the employer a powerful tool for dealing with the ups and downs of the economy and the necessity to adapt to versatile markets, it introduces for the employee uncertainty that the rhetoric of risk and predictability at the basis of the welfare-state is no longer able to govern and master (Evers and Nowotny, 1987).

One of the current social and political challenges is thus to make individual pathways secure in the new context of uncertainty that weighs on work (Supiot, 1999). But the categories established on the norm of full employment and the model of society that goes with it hardly manage to integrating these imperatives for diversity and flexibility. It is more generally the reduction of the concept of work to that of labor that is incriminated, to such an extent that an examination of the ongoing transformations entails a need to rediscover the diversity of meanings of work and to recast the relationship between the different facets of people at work: quite at the same time producer of value, creative individuals, and social beings.

In 1958 already, Arendt undertook a radical critique of this reduction that led, in her mind, to labor invading the political sphere, even crushing the latter in favor of the 'social.' Against the institution of labor as a general category of human action and its colonization of all the other fields of human activity, Arendt reminds us that it is merely one aspect among others of *Vita activa*. Doing so, she emphasizes a major differentiation between:

1. Labor, an activity of *anima laborans* governed by the human's needs of subsistence and reproduction, producing ephemeral things destined to be consumed;
2. Work, an activity of *homo faber*, producing lasting objects aimed at stabilizing human life; and
3. Action, *praxis*, which produces things that are inseparable from the actor and which only occur through interaction. Action thus constitutes for Arendt, the eminently public and political aspect of *V. activa*; a sphere that should not be contaminated by the invasive logic of labor and consumption.

Whereas Arendt deplored the progressive absorption first of work, then of action, by the reductionist concept of labor, the topicality of the relationship between work and action has since been renewed. Far from Arendts' claim in favor of a clear-cut dissociation between the sphere of labor, the one of work and the public sphere, their articulation has become a major political and social issue; notably because of the transformations of work, of labor statuses, and the growing part taken by the services and tertiary sector in the economy. In relation with the challenge of analyzing these transformations, the concept of work has opened up toward action, that is, work as activity. Several movements converged within the social sciences in favor of such a broadening of the concept of work. In 1982, Ralf Dahrendorf made a plea in favor of a conceptual shift from a labor society (*Erwerbsgesellschaft*) to an activity society (*Tätigkeitsgesellschaft*). Referring himself to Arendt's categories, he promoted an enlarged understanding of work integrating informal work, namely, domestic work and moonlighting (Dahrendorf, 1983). The feminist movement (Kittay, 1999) defended the same cause, initiating a debate on how to define and measure household work (Eichler and Albanese, 2007). Other authors seek for criteria of definition of non-market activities, like the "third person criterion" according to which "an economic activity is one which can be done by a third person without reducing its final utility value" (Hawrylyshyn, 1977). But the question whether one should or not limit the understanding of work to economic activity, that is to an activity that can be converted into an amount of money according to market rules, remains a crucial point of debate.

The shift toward a problematic of work as activity happened concomitantly with a revival of action theories in the social sciences, particularly the rediscovery of the pragmatist vein of the Chicago School. Pragmatism and interactionism have been, during the whole twentieth century, a strength of analyses and an answer to functionalism in American sociology of work, with scholars like E.C. Hughes (1958), A. Strauss, and their followers. Continental European social sciences have instead developed, as an alternative to the dominant functionalist paradigm of the 1960s, a structuralist approach mainly concerned with the status conferred on individuals by their jobs and the ensuing inequalities. The 1990s can insofar be characterized by a pragmatist turn in European social sciences (Joas, 1996/1992).

This turn contributed to spelling out the issue of work as action and activity, therefore taking into account a greater diversity of meanings of work (women's domestic work, voluntary and civic work, informal work, etc.) and exploring their moving frontiers with wage labor. It furthermore lead to envisaging work from the perspective of the interactions and conventions that preside over coordination among people at work (L'économie des conventions, 1989). Such an approach pays attention to the content of work in itself, to the kind of activity, products, people, and situations involved (Boltanski and Thévenot, 1989). After the major movement of standardization that characterized the history of the concept of labor and sealed its hegemony, the concept of work today is being redesigned to integrate the nature and the quality of what it produces, as well as work situations and people's capabilities (Zimmermann, 2011). It opens up to the analysis of a plurality of configurations of action (Salais and Storper, 1997/1993; Boltanski and Chiapello, 1999) taking account of the anthropological dimension of work.

By the same token, the uncertainties that weigh on national employment institutions, under the pressure of globalization and the constitution of supranational political entities (Habermas, 1999), have found considerable resonance in social sciences debates. After the supremacy of the national level, alternative scales of regulation and organization of the collective sphere are being reassessed, both from a practical and theoretical standpoint. In these matters too, the connection between economic and political transformations, on the one hand, and paradigmatic changes in the social sciences, on the other, is a close one. Once passed the postmodernist fever announcing altogether the end of work and history (Lyotard, 1984/1979), the twenty-first century opened an era of revising both the categories of organization of society built around work and nation, and their principles of intelligibility as they were defined by the social sciences. The challenges for a new conceptualization of work are numerous. Named globalization, sustainability, human development and capability, growing inequalities, ecology, etc., they require to rethinking work not only as an economical good, but as a human activity tightly intertwined with the other aspects of human life at both the individual and collective level.

Work Motivation

James M Diefendorff and Gina A Seaton, The University of Akron, Akron, OH, USA

Abstract

The study of work motivation focuses on understanding why individuals pursue particular activities at work as well as the amount of effort exerted and duration of persistence in pursuing activities over time. Work motivation research attempts to understand how individuals allocate their limited resources to competing demands at work, describing when and why specific activities are pursued. In this article, we elaborate on the role of goals as a central organizing mechanism through which motivated action is observed and discuss a variety of approaches aimed at understanding motivated behavior at work.

Motivation is often defined as an internal force that directs, energizes, and sustains behavior over time and across changing circumstances (Kanfer, 1990). As such, motivation is observed in the choices that individuals make regarding which goal to pursue (i.e., direction), the amount of effort they invest in attaining a particular goal (i.e., the vigor or intensity of action), and how long they are willing to pursue a goal (i.e., persistence). Stated differently, motivation pertains to how individuals allocate their limited resources to competing demands over time, describing when and why specific activities attract individuals' attention and limited resources. The study of work motivation represents an attempt to understand motivated behavior in the context of organizations, which introduces a variety of boundary conditions and unique contingencies that can impact basic motivational processes (e.g., compensation systems, externally derived goals, job characteristics, distinct social relationships, norms, and organizational culture; see Diefendorff and Chandler, 2011).

Before describing specific motivation constructs and theories, it is important to distinguish motivation from other influences on behavior. It has become axiomatic in the organizational behavior literature that behavior is the result of three factors: ability, the situation, and motivation. Thus, when determining whether motivation is operating, it is necessary to rule out the influence of ability and the situation on action. An individual may be very motivated but fail to perform because of a lack of ability or because of defective tools or equipment. Alternatively, a person may have little desire to perform a behavior, but may do so because a strong situation coerces action (e.g., an assembly line) or because he or she has a great deal of knowledge and experience and can perform the task easily.

Much of the research on work motivation takes the concept of goal as the central organizing mechanism through which motivated action is observed. We begin our discussion of work motivation by describing goals, goal-setting theory, and constructs thought to reside in the 'hub' of work motivation (Locke, 1991) as well as the self-regulatory processes involved in striving for goals over time (Carver and Scheier, 1998). Next, we turn our attention to describing two approaches aimed at characterizing the structure and phases of behavioral self-regulation. Finally, we discuss content theories of motivation that focus on why individuals pursue different activities and the ways that these reasons for goal pursuit impact self-regulation. The discussion in this article is intended to touch on some of the dominant approaches to understanding work motivation. As such, it is necessarily brief and incomplete. More detailed and comprehensive reviews of work motivation can be found elsewhere (e.g., Diefendorff and Chandler, 2011; Latham, 2007; Lord et al., 2010; Kanfer, 1990; Kanfer et al., 2008).

Goals and the Motivational Hub

Goals

Goals can be defined as "internal representations of desired end-states" (Austin and Vancouver, 1996: p. 338), with these desired states varying along several dimensions, including importance/commitment (i.e., low vs high), difficulty (challenging vs easy), specificity (specific vs general), temporal range (short vs long), connectedness complexity (isolated, simple vs connected, complex), and level of consciousness (conscious vs unconscious). Further, goals are shaped by both personal characteristics and situational factors. Goals are the dominant focus of motivation research, and their importance can be seen in their pervasive presence in theories of motivation. Some authors argue that goals guide and organize nearly all human activity (e.g., Locke and Latham 1990).

An important tenet of many theories of motivation is that goals are hierarchically arranged (e.g., Carver and Scheier, 1998; Lord et al., 2010). Near the top of this hierarchy exist superordinate goals, which tend to (1) extend relatively far into the future, (2) be relatively stable, and (3) be grounded in core aspects the self, such as personality, needs, motives, and values. Near the bottom of the goal hierarchy exist action goals that represent concrete behaviors individuals engage in at any given point in time. This level of the goal hierarchy is often the focus of employees' attention and regulatory resources during the workday.

As one moves down the goal hierarchy, each successive layer of subordinate goals is more tactical, concrete, and short term. Each subgoal can be considered a strategy (i.e., a means) for achieving the goal above it in the hierarchy. One's confidence for attaining a goal is influenced by the ease with which the subgoals needed to reach the higher order goal can be performed. Additionally, the value of a lower-level goal is determined, in part, by the strength of its relationship to important

 http://dx.doi.org/10.1016/B978-0-08-097086-8.22036-9

higher level goals. Thus, goals are best understood as embedded in a goal hierarchy with their characteristics being tied to their position in the goal hierarchy and the strength of their ties to other goals in the hierarchy.

Goal-Setting Theory

Given the large number of ways that goals can differ, research has examined how different goal dimensions affect performance. One approach to systematically studying the effects of different goal dimensions is goal-setting theory (Locke and Latham, 2002). Goal-setting theory is one of the most influential theories in the study of work motivation, describing how goal characteristics influence performance through the mechanisms of attentional focus, effort, persistence, and strategy development. A key finding from goal-setting research is that difficult, specific goals that are accepted result in better performance than do-your-best or easy goals (Locke and Latham, 2002). Goals with these characteristics are beneficial in that they reduce ambiguity and require individuals to expend more effort, better focus their attention, and persist longer over time. Moreover, as tasks become more complex, difficult and specific goals also produce more strategy development, which can enhance performance.

There are several boundary conditions and caveats surrounding the prescription of assigning difficult and specific goals. First, goal difficulty is determined relative to each individual's capability, with optimal effort exertion occurring when there is a good match between the demands of the task and an individual's skill (Locke and Latham, 1991). Thus, an assigned goal that is determined to be normatively difficult may overshoot the optimal difficulty level for some individuals and undershoot it for other individuals, both of which can result in lower motivation. Second, research has shown that goal setting must be accompanied by feedback that allows individuals to monitor their progress and make necessary adjustments to their goal-directed behavior (Locke and Latham, 1990). Goal environments that are not feedback rich can prevent goal-setting interventions from producing their intended benefits. Finally, research has shown that difficult, specific goals may harm performance when they are assigned for novel or complex tasks as they may inhibit needed strategy development (e.g., Kanfer and Ackerman, 1989). When first working on a task (i.e., early in the skill acquisition process), not assigning a goal may actually be beneficial as it can facilitate learning and strategy development, resulting in a better long-term performance.

An Expanded Motivational Hub

Locke (1991) described the motivational hub as containing goals, performance, and self-efficacy, and suggested that this is "where the action is" (p. 296) for goal pursuit. Building on these ideas, we contend that expectancy theory constructs (expectancy, valence, and instrumentality) and affect may also be a part of this motivational hub, as these dynamic constructs are closely tied to goals and have been shown to impact goal selection and goal striving. We describe each of these constructs and their links to work motivation below.

Valence, Instrumentality, and Expectancy

According to Vroom's (1964) valence, instrumentality, and expectancy (VIE) theory, when individuals are deciding which activity to pursue they evaluate the expectancy, valence, and instrumentality of the possible activities. These three assessments are thought to combine to represent the overall motivational force for a goal. The goal with the highest motivational force is then adopted for pursuit. *Expectancy* is the perceived likelihood that expending effort will lead to goal attainment (Van Eerde and Thierry, 1996), *valence* is the desirability, attractiveness, importance, or anticipated satisfaction with outcomes associated with a goal (Van Eerde and Thierry, 1996), and *instrumentality* is the perceived likelihood that goal attainment will lead to desired outcomes (i.e., if I perform at a particular level, I will receive the associated rewards; Vroom, 1964). Each of these judgments contributes to an individual's motivation for a given task; if any of the three judgments are zero, no motivation is said to exist.

VIE theory variables have received a great deal of attention in the literature, though support for the theory varies as a function of the level of analysis. Van Eerde and Thierry's (1996) meta-analysis found weak support for the theory when the tests were at the between-person level of analysis (i.e., comparing how individuals differ in expectancy, valence, and instrumentality for an action). However, the results were stronger for predicting preferences and effort when the analyses were restricted to the more appropriate within-person level of analysis (i.e., comparing how actions differ in expectancy, valence, and instrumentality within the person). In other words, empirical tests that matched the underlying theory (i.e., choosing among goals vs examining who is more or less motivated to pursue a particular goal) provided stronger support for the theory.

Self-Efficacy

Self-efficacy is a person's belief that he or she can perform the actions needed to attain a specified level of performance (Bandura, 1997), and is conceptually related to the expectancy concept in VIE theory. Self-efficacy is shaped by a variety of factors, with past experiences having the strongest influence (Bandura, 1997). Self-efficacy is a center piece of Bandura's (1997) social cognitive theory and was incorporated into Locke and Latham's (1990) goal-setting theory. As a result, self-efficacy is one of the most commonly studied predictors of task-specific motivation. In general, self-efficacy has been shown to have positive effects on a variety of motivational and performance outcomes across a large number of studies and research contexts (e.g., Stajkovic and Luthans, 1998). However, a stream of research in recent years has challenged the causal role of self-efficacy in positively influencing performance, with some researchers finding that self-efficacy is primarily a reflection of past performance (and does not *cause* future performance; Heggestad and Kanfer, 2005) and that the causal role it plays in influencing effort and performance can sometimes be negative (e.g., Vancouver and Kendall, 2006).

Recent studies have attempted to reconcile these conflicting findings. For instance, Vancouver et al. (2008) theorized and found support for a nonmonotonic and discontinuous model in which self-efficacy has positive effects up to the decision to pursue a task and then has negative effects as self-efficacy

further increases. That is, an increase in self-efficacy can lead individuals who would not pursue a goal to suddenly switch and decide to pursue the goal (producing a positive effect). However, after the person has adopted the goal, further increases in self-efficacy may lead individuals to become overconfident and, as a result, not exert as much effort in the pursuit of the goal, resulting in a negative effect of self-efficacy on performance.

Other research has also attempted to further clarify these conflicting effects. For instance, Schmidt and DeShon (2009) found that challenging circumstances led to a positive relationship between self-efficacy and performance (i.e., very confident individuals rose to the challenge following poor performance), whereas less challenging situations resulted in a negative relationship (i.e., very confident individuals did not exert as much effort as individuals with low confidence following successful performance). Further, Schmidt and DeShon (2010) found that ambiguity moderated the self-efficacy and performance relationship, such that under conditions of high ambiguity a negative relationship was observed, but under low ambiguity a positive relationship was observed. Together, these studies suggest that the self-efficacy and performance relationship is complex and that there are conditions under which high self-efficacy can be beneficial or harmful. More work on this interesting and complex topic is needed.

Affect

Motivation and affect are inextricably linked. Affect is thought to influence motivation both indirectly through cognitive processes and directly through unconscious processes. Seo et al. (2004) present a theoretical model in which these processes are explicated. In relation to indirect effects, they theorized that when evaluating goals or performance (especially in ambiguous situations) individuals use their current affective state to make judgments regarding expectancy, utility, and progress. Positive affect is thought to result in more favorable goal-related judgments as compared to negative affect. Consistent with this idea, Erez and Isen (2002) found that for more difficult performance goals, individuals in a positive mood had higher expectancy, valence, and instrumentality than individuals in a neutral mood. Further, Carver and Scheier (1998) argued that positive affect may signal that goal progress is adequate, leading individuals to reduce their subsequent effort. In contrast, negative affect may signal that goal progress is not sufficient and that greater goal-direct effort is needed.

Seo et al. (2004) also theorized that there are situations in which motivational processes are not mediated by conscious judgments. Instead, they argue that affect itself can be a motivational force that directly energizes an individual's goal-directed behaviors. Indeed, research has suggested that positive and negative affect trigger different motivational orientations, with positive emotions showing greater alignment with approach motivation and negative emotions show greater alignment with avoidance motivation (e.g., Neumann and Strack, 2000). Additionally, some research has shown that unconscious affective priming can shape goal-directed behavior (Aarts et al., 2007). The continued integration of affect and motivation processes represents an exciting direction for work motivation research.

Self-Regulation Approaches to Understanding Work Motivation

Now that we have described goals and constructs in the motivational hub, we turn our attention to the regulation of goal-directed behavior over time. Motivation is a dynamic process in which individuals self-regulate their goal-directed activities (Diefendorff and Chandler, 2011). Consistent with the definition of motivation provided at the beginning of this article, the self-regulation of goal-directed activities occurs over time and across changing circumstances. As such, many models of work motivation adopt a self-regulation perspective to characterize this process. Self-regulation may be described in structural terms that explain the interrelationship of self-regulation components or in terms of distinct phases in the self-regulation process. We elaborate on each of these perspectives below.

Structure of Self-Regulation

The basic structure of self-regulation can be characterized using the principles of control theory (e.g., Carver and Scheier, 1998). At the center of control theory is the negative feedback loop. As shown in **Figure 1**, the negative feedback loop includes a standard (reference value or goal a person is trying to attain), a comparator (for matching the standard against performance), an input function (for sensing current performance), and an output function (for changing behavior). The negative feedback loop operates as a continuous process in which individuals monitor and sense discrepancies between current and desired states and engage in behaviors to reduce any observed discrepancies. If no discrepancy is sensed, the person is expected not to make any changes to behavior. If performance is lower than the goal (i.e., a negative discrepancy), the output function is engaged, resulting in greater effort expenditure so as to bring performance into line with the goal and reduce the discrepancy. If performance is higher than the goal (i.e., a positive discrepancy), effort on the focal goal may be reduced and resources may directed to another goal that is awaiting attention. This discrepancy detection and reduction process is thought to operate continuously and automatically over time as conditions in the environment change (Carver and Scheier, 1998).

Phases of Self-Regulation

In addition to describing the cyclical process of self-regulation, some researchers have broken self-regulation into distinct phases and examined how motivational, cognitive, and affective processes differ across these phases. One common way to divide the process is into the phases of goal setting, goal striving, and goal revision (see Diefendorff and Lord, 2008, for more discussion of self-regulatory phases).

Goal Setting

Self-regulation begins with goal selection (or commitment to an assigned goal). The act of choosing or accepting a goal creates a discrepancy that individuals are motivated to reduce. Selecting an action goal involves choosing among different tasks to pursue (e.g., finish reading a book vs finish writing a report) or the level of performance to aspire to within a task

Figure 1 Structural model of self-regulation: the negative feedback loop.

(e.g., write five pages vs write ten pages), which can be done according to the VIE theory principles outlined above. The selection of an action goal can involve both conscious and nonconscious processes that take into account stable and dynamic aspects of the person (e.g., long-term motives, short-term affect) and situation (e.g., organizational culture, fluctuations in work processes).

Goal Striving

After an action goal is chosen, individuals must put forth effort to attain the goal. Effort refers to the amount of mental or physical resources devoted to a task. The more effort allocated to a task, the more the person is said to be motivated. Effort has been operationalized in a variety of ways including cardiovascular reactivity, resource allocation, and subjective experience of exerting effort. Some researchers have argued that persistence (another hallmark of motivation) essentially reduces to the same concept of effort in that both pertain to the amount of resources dedicated to a task during a period of time (Dalal and Hulin, 2008).

Individuals regulate their effort during goal striving by not only comparing their current state against the desired state, but also by matching their current rate of discrepancy reduction against their desired rate of discrepancy reduction (Carver and Scheier, 1998). In effect, individuals compare their actual rate of progress with a desired rate of progress and experience distinct affective states based on this comparison. If progress is faster than expected, individuals may experience a sense of calm or happiness, which leads to a reduction in effort on the task and allows the person to devote resources to other things. In contrast, if progress is slower than expected, the individual may experience anxiety and increase effort on the task. Goal striving continues until the goal is reached or a predetermined stop time is reached (i.e., a deadline).

Goal Revision

At the end of a goal-striving episode, individuals once again compare their performance against the goal to determine whether the goal was attained (Carver and Scheier, 1998). If the goal was attained, individuals may set a new goal within the same domain or decide to pursue a goal in a different domain. If the goal was not attained, individuals must make a choice on how to proceed. For example, individuals may decide to keep the goal at its current level and try again, they may decided to revise it (upward or downward), or they may abandon the goal altogether and pursue a new and/or different goal. Of course, in many work environments where competing demands are plentiful, individuals may also decide to table the goal and momentarily direct attention to another activity, returning later to the decision of whether and in what way to revise the goal.

In general, research investigating goal revision has suggested that individuals with large, negative discrepancies (i.e., one's performance was below the goal) tend to revise their goal downward in future goal-striving episodes, whereas individuals with positive discrepancies (i.e., one's performance was above the goal) tend to revise their goals upward. In addition, these relationships may be affected by both the time left to pursue the goal and the causal attributions that individuals make for performance (Donovan and Williams, 2003).

Content Approaches to Understanding Work Motivation

In contrast to focusing on the motivational hub or the structure and phases of self-regulation, *content theories* of motivation emphasize the ways in which motivation may differ between individuals and the effects of these differences on self-regulation. Content theories focus on why individuals pursue activities and how the reasons for goal pursuit alter the ways in which self-regulation proceeds. Several theories may fall into the category of content approaches to motivation, but a few have been frequently applied to organizational contexts and are discussed in more detail here: Deci and Ryan's (2000) self-determination

theory (SDT), Dweck's (1986) goal-orientation theory, and Higgins' (1997) regulatory focus theory.

Self-Determination Theory

SDT (Ryan and Deci, 2000) emphasizes the satisfaction of basic human needs for autonomy, competence, and relatedness as a key driver of motivated behavior. In contrast to many theories of motivation, which emphasize the quantity of motivation (e.g., goal-setting theory), SDT emphasizes the idea that qualitative differences in motivation also matter. Specifically, a key contribution of SDT is that it describes a continuum in which goals may be pursued for different reasons, ranging from being intrinsically motivating at one extreme to being extrinsically motivating at the other end. The theory suggests that these different motivations can all lead individuals to act, but they may have different implications for performance and well-being.

According to SDT, intrinsically motivating tasks are interesting, enjoyable, and spontaneously pursued by individuals. Such motivation is experienced as autonomous and self-determined (Deci and Ryan, 2000). In contrast, extrinsically motivated tasks are pursued because of external contingencies, but can be experienced as controlling or autonomous depending on the extent to which the contingencies have been internalized by the individual. As such, SDT describes several different types of extrinsic motivation. External regulation is the least internalized form of extrinsic motivation with individuals pursuing tasks because of rewards or punishments present in the environment. Introjected regulation is the next form of extrinsic motivation, with individuals pursuing goals because they have internalized and come to self-administer the rewards and punishments for the goal. Often, individuals who experience introjected motivation pursue tasks because they would feel guilty if they did not. Identified regulation reflects a more internalized form of extrinsic motivation whereby individuals understand the value of the goal and pursue it based on that understanding, but they have not come to personally value the goal and the reasons for its pursuit. Integrated regulation reflects the most complete internalization of an extrinsic goal whereby individuals have come to personally value the goal and experience it as important. The goal is not inherently interesting or fun (so it is not intrinsically motivating), but it is valued, important, and experienced as autonomously motivating. Finally, in contrast to the motivated behaviors described above, SDT also recognizes that some behaviors may be amotivated, which means that individuals are not able to provide a reason for why they engage in them.

Ryan and Deci (2000) argued that some goals are more consistent with satisfying an individual's basic needs than others. In particular, striving for autonomous goals may lead to greater need satisfaction and better well-being, whereas striving for controlled goals may lead to the thwarting of one's needs and worse well-being. A key finding from research on SDT is that more autonomous forms of motivation are associated with better performance on interesting or complex tasks. However, differences between autonomous and controlled motivation are not observed for boring or mundane tasks (Koestner and Losier, 2002). Further, autonomous motivation is positively associated with well-being and job attitudes. Thus, both forms of motivation may lead individuals to perform a behavior, but autonomous motivation better satisfies psychological needs and leads to greater well-being compared to controlled motivation.

Goal Orientation and Implicit Person Theories

Goal orientation refers to differences in how people interpret and respond to achievement situations (Dweck, 1986). Research has identified two distinct goal orientations: performance and mastery. Someone high in performance goal orientation focuses on demonstrating ability and defines success or competence by comparing oneself to others, either by demonstrating competence relative to others (performance prove orientation) or by avoiding displays of incompetence relative to others (performance avoid orientation; Dweck, 1986). In contrast, an individual with a mastery goal orientation focuses on developing skills and abilities and defines success or competence against internal standards (Dweck, 1986). The commonly accepted view is that a mastery orientation is associated with an adaptive behavioral pattern (e.g., selecting challenging tasks, setting difficult goals, persisting in the face of obstacles), whereas performance approach can be adaptive or maladaptive depending on the circumstances, and performance avoid is maladaptive.

Mastery and performance goal orientations are grounded in implicit person theories (Dweck, 1986). According to this view, individuals vary in the degree to which they view attributes and abilities as malleable (as opposed to stable and enduring). A belief that human attributes are malleable and that effort and experience can improve one's standing reflects an incrementalist implicit person theory. A belief that human abilities are fixed and that effort and experience cannot improve the situation reflects an entity implicit person theory (Dweck and Grant, 2008). Research has shown that implicit theories are associated with differences in reactions to failure. For entity theorists, failure is viewed as a reflection of the self and thus, is experienced as threatening. Accordingly, these individuals tend to engage in strategies aimed at preventing or hiding failure (e.g., choosing easy tasks, self-handicapping, or withdrawing from tasks; Dweck and Grant, 2008). In contrast, incremental theorists view failure as an opportunity to learn (Dweck and Grant, 2008). As a result, incremental theorists enjoy learning new things because they view them as a way to increase their ability. Consistent with these ideas, Robins and Pals (2002) found that entity theorists adopted performance goals and displayed less adaptive behavioral patterns when faced with challenge, whereas incremental theorists adopted learning goals and displayed more adaptive behavioral patterns when faced with challenge.

Regulatory Focus Theory and Approach/Avoidance Motivation

According to regulatory focus theory, goal-directed behavior operates differently for individuals high in promotion focus compared to individuals high in prevention focus (Higgins, 1997). A promotion focus refers to a motivational strategy that is approach oriented and concerned with positive outcomes, accomplishments, gains, and aspirations. A prevention focus, on the other hand, refers to a motivational strategy that is avoidance oriented and concerned with safety,

duties, and avoiding negative outcomes. For prevention-focused individuals, goals are seen as obligations, rather than desired standards. In this way, promotion-focused individuals seek to reduce discrepancies between actual and 'ideal' selves, whereas prevention-focused individuals seek to minimize discrepancies between their actual and 'ought' selves.

Individuals with these different motivational foci also exhibit distinct behavioral patterns and experience different emotions in the goal-striving process. For example, individuals with a promotion focus tend to experience eagerness when goal striving, feel joy when goals are attained, and feel sadness when goals are not attained (Brockner and Higgins, 2001). On the other hand, prevention-focused individuals are cautious during goal striving, feel relaxed when goals are attained, but feel nervous when goals are not attained (Brockner and Higgins, 2001).

Consistent with the approach/avoid distinction outlined by regulatory focus theory, Gray (1982) theorized that behavior is derived from two biologically based motivational systems: the behavioral activation system (BAS), an appetitive or approach system, and the behavioral inhibition system (BIS), an aversive or avoidance system. High BAS sensitivity is reflected by a heightened reactivity to signals of reward or nonpunishment and a perceptual readiness and strong emotional responsiveness to such stimuli (Gray, 1982). High BAS sensitivity is associated with under arousal, impulsivity, a strong drive to attain goals, and the experience of positive emotions. High BIS sensitivity, on the other hand, is reflected by responsiveness to signals of punishment or nonreward and a strong sensitivity to and perceptual readiness for negative stimuli. High BIS sensitivity is associated with low levels of behavioral activity and the experience of negative emotions. Consistent with this theory and research, Elliot and Thrash (2002) found that BIS sensitivity, neuroticism, and negative affectivity loaded on a common avoidance latent trait, and BAS sensitivity, extraversion and positive affectivity formed a common approach latent trait. Additionally, the authors found that these latent traits predicted the selection of achievement goals (i.e., mastery, performance approach, and performance avoid) in theoretically consistent ways (Elliot and Thrash, 2002).

Conclusion

The study of work motivation has seen significant advances in recent years in our understanding of motivational processes, antecedents, and outcomes. In this Encyclopedia article, we have highlighted what we believe to be some of the most influential concepts and perspectives in this area of study. However, it is important to note that we have only scratched the surface of empirical findings pertaining to the field of work motivation. Indeed, researchers have explored a myriad of issues that fall outside the scope of this article.

Although the field has made significant strides in terms of understanding motivation at work, there is also still much to be learned. Some new and exciting directions to take the field of work motivation include examining: (1) the role of conscious (i.e., self-attributed) and unconscious (i.e., implicit) motivational processes, (2) the substantive role of time in shaping motivational processes (e.g., effects over time and within-person dynamics), (3) group motivation, and (4) integration of multiple theoretical perspectives, such as the investigation of structural models of self-regulation with content theories like SDT. The advances in work motivation research outlined in this article, coupled with emerging themes in the study of motivation, make it clear that this area of study is vibrant and will remain so in the coming years.

Abstract

Presented is the centrality of work in the human existence, including work's personal and social dimensions. Anglo-Saxon folk and intellectual thought about work exclude much laboring activity. Reviewed are work's purpose, gain, control, temporal synchronizations, and monetization. Work is an adult's principal mooring in society. Discussion includes employee participation, social control of 'progress,' division of labor, gender, industrial policy, computerization, alienation, deskilling, training, outsourcing, unionization, retirement, the 'new economy,' and the 'the end of work.'

Work is central to the panhuman existence. Work is above all a sociocultural phenomenon. Humans engaged in work are primarily *Homo sociologicus* rather than *Homo economicus* (Dahrendorf, 1983 [1968]). For providing livelihood, generating creations, and producing other outcomes, work concerns culturally patterned mental, physical, and emotional exertions. The sociology of work investigates the opportunities and constraints of work. Investigation covers the broad, patterned context for work as it encompasses individuals, supports communities, shapes nations, and binds countries. Workers in modern society spend much of their waking time on the job and in its commutation (Gamst and Helmers, 1991).

'Modern society' has some degree of an ideological and organizational basis of bureaucratic industrial capitalism or socialism, both influenced by the global market. Modern bureaucracies have both efficiencies and inefficiencies for controlling work. In modern society, to varying extents purpose for an organization is negotiated both internally from its members and externally from outside organizations including those governmental. Work organizations include purposeful for-profit businesses, governmental units, labor unions, schools, churches, charities, advocacy groups, and military bodies. A work organization has a 'formal' aspect, where action accords with its rules, procedures, and policy, and an 'informal' aspect, where members' loose alliances and adaptable partnerships influence performance of actions. Regarding everyday life in all societies, the sociology of work is an instructive subject for extensive reflection in conceptualization and manifold relevancy in practice.

In the twin disciplines of sociology and sociocultural anthropology, the study of work has long been a central interest, and it pervades much of the disciplines' published research (Abbott, 1993; Gamst, 1977, 1995; Kalleberg and Berg, 1987; Wallman, 1979). In this article the product of both disciplines has the label 'sociological.' 'Work' has perhaps the widest meaning of any word in English. It is a culture-bound, scholarly concept and folk idea. This article examines value-laden meanings and dimensions of 'work.' Every society (and subsociety) has particular patterns of rewards for work and distributions of gains from work. Not all work has factors of production institutionalized in price-making markets for labor, products, and land.

Selected History of the Sociology of Work

Few ethnographic monographs about nonwestern societies exclude information on work. Into the twenty-first century, the twin disciplines have depicted the centrality of work in community studies in the United States and Canada. Employment and its access are a vital interest of the fieldworker studying a community, often from an ecological perspective. Pioneering research on work and workers in North America apart from community studies includes that of Whiting Williams, beginning in 1918, on the human relations of employees and employer (Williams, 1918). Earlier, Emile Durkheim (1947 [1902]: 13) discussed rules that "fixed the responsibilities of employers and workmen, as well as the duties of employers toward each other." Durkheim's ideas have expanded into a French sociology of work (Bouvier, 1994; Tanguy, 2008). Castillo (1997) cautions against relying solely on English-language studies of work and reviews other pertinent sources (see also Helmers, 1993; Spittler, 2008).

With the advent of the experiments and observations regarding workers in the Hawthorne plant of Western Electric, by 1930, the twin disciplines entered their phase of the social science of industrial work, then often having a social psychological bent (Carey, 1967). Studies of work received legitimization in 1946, when the American Sociological Association formed its Section on Industrial Sociology and again, in 1951, when Delbert Miller and William Form wrote the first textbook, *Industrial Sociology* (Miller and Form, 1951). Originally, work-studies were a variety of empirical emphases not having a characteristic conceptual framework or methodology. Workers display the ordinary range of social behavior.

Organizations of work, from corporations to cliques on their jobs to peasant and forager work groups, are components of the greater human society. In studying modern societies, work relations are part of most conceptualizations of social structures and role information. Researchers frequently collect information in a workplace. Sociological study of work gradually diverged into a number of conceptual and methodological directions. Nevertheless, organizations remain a focus of the study of work (Perrow, 1986).

Occupational sociology's main interest is in studies of work (Pavalko, 1988; Volti, 2008). Occupations are purposive and are enacted by individuals or groups – either a singleton craftsperson, artist, or consultant or a socially linked number of like positions. Occupational hazards are a growing concern of research (Nichols, 2005).

Research on work broadened to encompass many emphases and overlapping subtopics, from gender issues to division of labor. Work research gradated into investigations conducted across disciplines, such as on organizations, social control,

industrial relations, and role theory. Organizational role theory examines role behavior in the workplace, often to increase productivity. Given all the research, what is 'work'?

Work as Culture-Bound Idea

Knowledge does not exist supra culture; thus, in the English-speaking realm, one must first examine the Anglo-Saxon cultural context of work. Language does not determine cultural outcomes. But it is a 'color filter' through which we perceive the world in expressions of our native technologies of work and their procedures, values and norms, produced property, and distributions of the fruits of labor. Work is the broadest English word for both the process of doing something and the state of something done. Work is viewed ambivalently. It is a moral necessity and the deity's curse of travail upon humankind ('in the sweat of thy face…'). As etymologically rooted and in folk views, the conception of work is broadly viewed as concerning all endeavors.

Many social scientists, however, attempt an analytically useful narrowing of the definition to include the creating of goods and services valued in a society. But valued by whom? As Melville Herskovits (1952) explains, the phenomena of value regarding things exchanged are understandable only as a part of a specific culture or a subculture. Adriano Tilgher (1958) says that because economic value is always relative, so is assessing the work creating it.

The social value of work, then, depends upon the socialized view of the observer, varying within a specific society. Managers of antebellum southern railroads and their corporate slaves had differing views of the nature of value created.

As with other issues in the sociology of work, for example the management-oriented studies spawned by Hawthorne, the definition of value of work resolves into whose ox is being gored or fed (Carey, 1967). A societal disruption, however, could be eufunctional for at least part of a society. Thus, an intensive strike after which workers lose their employment is not always dysfunctional to labor overall. Locomotive engineers and switchmen decisively lost the bitter strike on the Burlington road in 1888. Management's 'victory,' however, proved so costly to shareholders that other railroads began to recognize unions. If not definable by value, work has useful perspectives in various dimensions.

The Dimensions of Work

Work has a 'personal dimension' in defining the self, necessarily in relation to roles of others, and in obtaining positive affect from community members (Watson, 2008: pp. 251–256; Budd, 2011: pp. 143–161; Schemien, 2012). This dimension of identity has a strong hold on all humans, in nonmarket and market societies. In Africa, the Wayto hippopotamus hunter seeks his villagers' recounting of his prowess as a killer of game; the Qemant plowman seeks community recognition as a good husbandman. In American inner cities, for some streetcorner men, job experiences and consequent job fears constantly intimidate them. Apprehensive about an opportunity to work, they stand overwhelmed by experience (Liebow, 1967). Work greatly affects the integration of personality. The personal dimension does not exist apart from the social dimension.

Work's 'social dimension' concerns interpersonal relations as much as productive output. Most behaviors at work are comprehensible at the collective level. Individual self-interest is dampened by behavioral prescriptions, including values, norms, attitudes, and etiquette. Moreover, in modern society, with its atrophied bonds of kinship and limited ties of community, work in groups provides opportunities for the close interactions that all primates require, including humanly exchanging positive affect and releasing tensions in a 'support group.'

Each society structures work in a construction of time. Even in so-called timeless foraging and agrarian societies, space could not be used effectively without some kind of time reckoning for coordinating work. A Wayto fishes at the appropriate hour and hunts during seasonal movements of game. A Qemant plowman looks at the sun and reads time to within half an hour, sufficient for his community's needs. To coordinate industrial transportation, North American railroads developed standard time zones. Factory shifts must be organized by the time clock. For modern needs, scientists created the microsecond. Timing in industrial societies refers to temporal modes, including frequency, synchronization, and duration. Without such timing, society's work becomes dysfunctionally independent instead of functionally interdependent. The clock, more than the steam engine, was the serpentine machine in the garden of agrarian societies.

Anglo-Saxon folk and intellectual thought about work exclude much laboring activity. Some activities are not considered work when the time and exertion seem sporadic and little planned, the activities are only somewhat related or are unrelated to an institutionalized product (purpose), or the activities are commonplace. For utility as theory, a concept of human work must be valid across cultures and not bound by Anglo-Saxon patterns. When looking for the meaning of 'work,' it must be determined whether work must be purposeful and gainful and whether livelihood is viewed cross-culturally.

Work as Concept

A biological exertion involving energetic activity in motor acts coupled to thought has expression in culturally patterned work. A purely mental activity such as planning a task is work. Work as solely a motor act, apart from related thought, probably does not occur.

Because work is social, even when done in isolation from other humans, it is enmeshed in the collective conventions of a society. A person's work activities ordinarily intertwine with activities of others in role groups for producing, exchanging, and consuming goods and services. A work role is a cluster of attributes and expectations for a work status, a social position in a society occupied by a person. Even when work has performance distant from other persons in a group, it is enacted regarding the group.

Should exertion be 'purposeful' to qualify as work? Purpose overlaps with relative social value. The issue remains: purpose as defined from whose perspective? Canadians each perform

the same exertion and learned technique in felling a tree as an employed lumberjack, a tree farmer, a thieving 'timber pirate,' and a vandal. In economic parlance, the first two persons purposefully 'add value,' the third and fourth do not. To the extent that defining work depends on purpose, this characteristic is culturally relative.

Work could be defined as 'gainful' (simply, producing a gain) such as a livelihood earned in a nonmarket, transitional, or market economy (Applebaum, 1984). Broadly considered, gainful work does not require market exchange or money. Work is not always monetized and market-oriented (Williams, 2005). It could be coerced, as in slavery. The gain could be either an increment or a saving of something valued, incorporeal or material. It could be generalized reciprocity: a shaman reciprocates séances for sundry goods and services from community members. It could be collection-redistribution: a chief collects part of all goods and services produced and redistributes some to the chiefdom's members in kind and as political and other administration.

In modern societies, an individual has multiple statuses for 'gainful' work. A woman might be a homemaker rewarded by familial gratifications, a corporate executive paid in the market, a community volunteer given 'positive affect,' a coordinator of a food cooperative compensated in kind, and a member of a congregation striving for 'eternal life.' 'Livelihood' work supports a human's life (one's biological requisites) and life way (one's sociocultural requisites). With such a broad conception of livelihood, fewer kinds of exertion have exclusion as work.

Work in Modern Societies

Although a conception of work must be cross-culturally valid, much of its study concerns modern societies, which are industrial or industrializing, including an empirical, scientific, secular worldview and having dominant market exchange. In industrial society, few remain primary food or craft producers. People consume goods and services created outside their local communities. With an infinitesimally particularized division of labor, they gainfully work mainly for increments and savings to enhance their standards of consumption. Technological devices enormously multiply exertion in work with a consequently great personal productivity. By hoe, a Plains Indian, tilled 0.1 of an acre annually, but with machines, a Plains farmer tills 2000 acres annually. Although a concept of work does not depend on money, in today's market economy, it is the acme of activity. Sufficient money allows great independence from kinship bonds, community ties, and role expectations.

Because monetarily paid work is a central identifier of the modern self, the characteristic used as a person's overall social label and assessment is occupational status. After the ritualistic 'How do you do?' comes the probing 'What do you do?' Work furnishes a person's basis of social power, reputation based on achievement, and economic and other welfare.

In its concomitants, loss of modern work could mean the severing of one's principal mooring in society. The largest medium of monetary savings, the house, can be lost. In the United States, vital health insurance is terminated, and retirement credits are not accrued. Furthermore, the job delimits the kind of neighborhood along with the personal safety and property security obtainable. It determines the quality of housing inhabited. It influences the education and opportunity for children. It also restricts who will be friends, neighbors, and co-workers. Above all, the job allows a reassuring, predictable routine in an otherwise hectic life.

Social Control of Work

Coherence in scientific study rests on a central notion. In the twin disciplines, the notion might be 'social control,' their most widely used concept but about which no agreed definition exists. The term could mean an underlying social process, a social mechanism delimiting behavior, or a scholarly model for analysis. Most conceptions, however, concern norms (a culture's prescriptive 'shoulds,' 'oughts,' and 'don'ts') and the ways in which social organizations change while preserving some societal stability (Gibbs, 1994).

It is useful to conceive work organizations as 'contingent,' open systems in which no single managerial model is universally most efficient. Management suitably adjusts a work organization to the changing contingencies of the market, political pressures, peoples' demands, and technology by adjusting operations to its particular environment. Managers' adjustments form an organization's characterizing kinds of effectiveness by responding to contingencies (Donaldson, 2001).

Despite much writing about change in business organizations, McCabe (2007) finds that their patterns continue to be much the same as those of the past. Control maintains social relations that are not equally beneficial to the differing interests of all the involved actors, as depicted in the innumerable studies of work and reactions to controllers of work. Work organizations have formal and informal purpose and structuring of tasks and responsibilities. Informal social relations conflict variously with formal relations.

'Industrial relations' constitute contests for social control between employers and employees (sometimes with direct government involvement). Social control of work has a number of forms. These include bureaucratic, by formal rules and procedures; technological, by devices limiting or monitoring action; and collectively occupational, by grouped workers defining, in some part, the terms, conditions, and content of work. A pivotal question in studying control is, how are workers forced to act in ways not serving self-interest or worker-group interests? And what is the ill-defined boundary of their alternative, serving societal and private corporate interests?

Employee Participation

In the 'new industrial relations,' the strong control of work by managers is reclad by 'cooperative' programs, such as quality circles, team concept, and employee involvement. For unionized workers, participation in the programs necessarily broadens the character of their labor–management relations. A cooperative program, if fully developed and controlled through bilateral negotiations, could foster mutual benefits.

Participation programs, however, are sometimes created in trendy public relations (naively?) overlooking the opposing goals and highly consequential exercises of social control in the relations between labor and management. A large business organization possesses great social power, alone and in coordination with similar firms united in associations having great influence on government.

Unorganized employees, and sometimes those organized, are at a great disadvantage regarding power relations and abilities to exercise social control in the market. In its traditional adversarial role of countering union social control through cooperative programs, management can usurp union responsibilities and pose as a benefactor of employees. Cooperation could allow a transition from powerful collective to powerless individual bargaining for employees. In true employee participation, management must surrender some of its social control of workers. Genuine cooperation in work is fully bilateral, thus a partnership. It can be effected only by near equals in social control. This has not yet been the case. The global market pressures on wages and conditions of employment are inexorably downward.

Social Control of Technological 'Progress'

Business practice in North America includes a sectarian, 'laissez-faire' ideology promoting technological 'progress.' A tenet of such practice is the view that workers, their families, and their fellow community members must suffer the consequences of progress without redress or complaint. Technology, however, is not a neutral force or an impartial hand for advancement in an industry, for shaping society or for influencing an individual's life. Technological change in work receives guidance from visible hands, according to the goals of private firms, public agencies, and other organizations, including unions and advocacy groups. In business, only rarely does management effect social control solely through technology. Ultimate control comes through the bureaucratic mechanisms of a firm, thus from managerial norms. The high value North Americans place on technological change masks what seldom changes: the social controls shaping technology and its policy and, thereby, society.

Division of Labor and Gender

In foraging societies, occupational Jacks- and Jills-of-all-trades exist–hunters and gatherers. As technologies related to plant and animal domestication free some persons from primary food getting, a true division of labor, with occupational specialization, develops in addition to the universal natural division of labor by age and sex.

Despite the true division – including specialization of work technology within segments of a society or separation of a particular technology into its component techniques, or both – division by sex remains everywhere. A specific society assigns to each biological sex a number of gender roles that are mainly learned culture. The roles are normative results of socialization, including those regarding work. Not only do the conventional roles delimit what is 'male' and 'female' but also what is appropriate work for each sex.

Because a great overlapping range of somatic and mental characteristics exists for males and females, a similar range of tasks performed equally well by each sex obtains. Cross-culturally, almost no work roles are exclusively men's roles. Among the Hopi, women do the construction of multistory houses; among the Dahomey, women were the assault troops; and in many African societies, women have apical political statuses. Whatever a man can do, a woman can do equally well, with few exceptions that are related mainly to somatic strength.

Nevertheless, occupational and work-role sex typing is dominant even in industrial democracies. At Christmas-time, a boy customarily receives a pink nurse's kit and a girl, a black doctor's kit? Such socialization for conventional aspiring to statuses of work is multistranded throughout the fabric of a culture. Some feminist scholarship explores the relations among capitalism, patriarchy, and job segregation. Although these neo-Marxist studies are illuminating, they do not explain similar segregation in the patriarchal, plow-agricultural societies. These might additionally feature other sex typing, such as clitorectomies, infibulations, and familial honor-killings of females.

In industrial societies, occupational sex typing of women limits their kinds of work, levels of compensation, and ranges of beneficial concomitants of work. Restricted compensation opportunities foster women's dependence on men, with increased exploitation by men. Moreover, work prejudice against kinds of people restricts societal efficiency.

Focus on the workplace ignores the importance of an unpaid wife at home supporting a successful husband at work. Such economic exchanges between social unequals are at odds with the folk category of the self-made man. Not only is the workplace a site of male exploitation of women, sexual and otherwise, but it is also a locale for behaviors from flirting to consensual sex. Not just sexual harassment but additionally sexual pursuits have a workplace arena (Williams et al., 1999).

The Changing Nature of Work

In industrial societies, the future of work could include not enough of it to permit, for all, the earning of middle-class compensation (Simpson, 1989). Competition in the global market engenders a massive deindustrialization, with the loss of adequate jobs for those with high-school levels of education or less. Globalization (see Edgell, 2006: pp. 182–203; Volti, 2008: pp. 39–58) integrates national economies into one price-making, capitalist whole, even for so-called socialist states. Return on capital is the ultimate arbiter of whether a business fails or succeeds and jobs are extant. Generally, with rationalization and automation of work a country's standard of consumption rises.

A new industrial revolution dawns in additive manufacturing (so-called 3-dimensional printing) in which a digital materials 'printer' precisely forms an object by successively layering material into final shape (Grenda, 2012; Anderson, 2013). This fledgling technology replaces the traditional subtractive machining or forging of an object to shape. Developers can produce concept designs of objects in a few hours. Thus, production industries face radical transformations with redundancies in the world of work and its traditional tasks.

Production workers in developed countries must compete with global cut-rate labor. In the North American job market, employee loyalty has become a one-way street. Overnight, jobs can be eliminated in the thousands within a single firm, sometimes after its leveraged buyout. Some terminations are psychologically brutal.

Industrial Policy

Industrial policy involves a national plan and government involvement, ranging from pronounced to weak, for helping industries, including increasing and protecting their jobs. Industrial sectors and government agencies are coordinated in selected activities, and the former receive protections, grants, loans, and tax incentives for particular businesses. The developing counties benefit from such policies, and the developed countries have gained from it across time (Altenburg, 2011). In the United States, the Internet, satellite technology, and various forms of transportation benefit from industrial policy. However, especially when labeled as such, the policy is ideologically controversial, including regarding growth in jobs.

Computerization

Computer control and the handling of information and electronic communication both deskill and eliminate jobs. The blitz of combined computing and instant electronic communications change work and life ways. Watson aptly summarizes these changes as including computer-enhanced products; rapid design and testing of products; production of things by automatically controlled tools, robotic devices, and production lines; administration and monitoring of work; and control and determining of distribution of goods and services. Professionals tap enormous ranges of databases in medicine, law, engineering, and other professions, thereby using the accumulated experiences of numerous peers (Watson, 2008: pp. 168–171). Consequent to the computerization of work is its intensification and a narrowing of the scope for initiative (Gallie et al., 2004).

With computerization, products enter into a new age of custom specification. The worker produces and the consumer receives precisely the product desired. Information services have automation, often frustrating consumers, ranging from hierarchically organized call centers to a firm's voice mail directions for connections. Nevertheless, through the Internet, a surfeit of information is available.

Computer-controlled supply chains components of manufacturing and its jobs are global. These parts have selection for effectiveness through their design and fabrication by many specialists around the world. Production in one country depends on components from another. After the tsunami of 2011, Japanese factories could not produce certain automotive components, thereby disrupting the manufacture of automobiles globally.

An issue for computerized operations is, to what extent does reduction of task content reduce operator responsibility for control of a procedure, including, under operational circumstances, at the edges of the operating range and the environment? What are the boundaries between human and computer responsibilities and, does the human have sufficient time, observability, and directability for handling the procedure, as in aircraft, boat, and locomotive control? As long as an operator is responsible for outcomes and can lose any certification, he/she must have effective authority and realistic ultimate control over solving a range of problems in the human–computer interface (Gamst and Gavalla, 2005: pp. 99–109).

Alienation in Industrial Work

The Marxian-rooted idea of 'alienation' (estrangement) in unskilled and semiskilled work concerns subjective feelings about paid toil. Such lack of job satisfaction occurs in capitalist and socialist societies. Isolation in the work group, a feeling of powerlessness, and insufficient remuneration are dimensions of work alienation. This finds expression in the North American workers' anthem "Take This Job and Shove it." However, even assembly-line workers might find satisfaction of the job supported by their employment (Blauner, 1964; Edgell, 2006: pp. 28–47).

Deskilling and Upskilling

Automation and reorganization of work created a controversy about the existence of 'deskilling' under capitalism, a continuous lowering of levels of skill throughout a national economy, leading to an unskilled proletariat. The notion of 'upskilling,' in a society characterized as knowledge-based and post-private-property, criticizes the idea of deskilling (Edgell, 2006: pp. 48–72).

Neo-Marxist 'deskilling' is a form of social control of workers through a minute division of labor, furthering organizing work into simple, repetitive tasks involving few mental reflections. Although a good number of crafts and some professions have had deskilling through the present, no deskilling throughout an overall industrial economy exists as yet. Professions, often protected by their gatekeepers, have specialized knowledge requiring extensive education and occupational training for their power-wielding roles (Volti, 2008: pp. 97–116).

Training and Education

In modern societies, opportunity for 'good' jobs requiring slight instructional background diminishes. Operational redundancy in targeted jobs continues. Technical backgrounds necessary for employment in the United States and Canada raise questions about the requisite kinds of preparation for jobs and careers. Politicians at the highest levels mindlessly advocate everyone 'going to college,' a course sometimes leading to a low-compensation retail position as an 'associate.' Values and norms for 'blue-collar' work wither against those for earning a BA in art history, liberal studies, or comparative literature. Students avoid as too demanding STEM (science, technology, engineering, and mathematics) studies. Rejected as undemocratic is the education and training found in Germany's trade tech emphases coupled to meaningful, job-acquiring apprenticeships.

Rudderless national educational policy has costs for individuals and society. Several North American railroads, however, prepare future employees for rewarding jobs at a community college or a corporate campus. Some German firms introduce their job instruction in the United States.

Education of managers and workers plus legal remedies can foster diversity and lessen its impediments in the workplace (Volti, 2008: pp. 137–156). Diversity is a concern in most developed countries (DiTomaso et al., 2007).

Outsourcing and Offshoring

Businesses sometimes reduce jobs and foster an erosion of remuneration by having work done outside the firm more cheaply and, when in another country, sometimes with fewer workers' rights. 'Outsourcing' of work has a business contracting to have some of its functions, often regarding information and administrative services, performed by an independent firm, located in or out of country. 'Offshoring' is 'outsourcing' when a business moves functions, such as manufacturing or information and administrative services, from the home country to another country (Davis-Blake and Broschak, 2009). China and Mexico are common locations for offshoring production and India for the two services plus assessing medical information. Threatened are even the developed world's jobs in the STEM professions.

The Union Label?

Trade unions contest management for social control in some workplaces. In America, union membership declined from 26.7% of the workforce in 1973 to 13.6% in 2011. This declining unionization has lowered wages, in part through employers' aggressive positions hostile to unions and through changes in applying and processing labor law, thus contributing to union weakening, including its means of increasing remuneration. The weakening of unions contributes to the faltering wages of the middle class. The union premium on wages and benefits compared to those of nonunion members is 17.3% for men and 9.1% for women. Unionized workers have 28.2% greater likelihood to have health insurance coverage provided by the employer and a 53.9% greater likelihood of receiving a pension from the employer (EPI, 2012: pp. 1–3). Unionization provides an ever declining wage advantage to American workers.

The future of the labor movement, however, is clouded (Durrenberger, 2007). In the United States and Canada, trade unions have diminished in union density, organizing success, level of labor actions, and political influence. Reasons for this decline include union sloth; the law as enacted and then interpreted by the courts; globalized competition; management-labor 'cooperative' programs; and a neo-liberal philosophy embraced by the large political parties. For union success, new forms and policies in the labor movement must be created including, multi-employer bargaining, removal of legal impediments to organizing, and coordination with community, advocacy, religious, and ethnic organizations to further mutual goals (Clawson and Clawson, 1999).

Retiring from Work

Macroeconomic changes affect the retirement income previously earned by workers. When government policy maintains a near-zero percent interest for loans, it harms projections of pension funds and impoverishes retirees relying on interest-bearing accounts. Policy for near-zero rates promotes spending rather than prudent saving. Beginning in 2007 real interest rates (after inflation) became negative. In the United States alone, about 10 000 workers retire every day. Is neediness a reality of their future?

Working in the New Economy

During the 1990s, changing the world of work, a 'New Economy' dawned based on computerization, communication and information technologies, e-commerce, and outsourcing (Grint, 2005: pp. 355–384; Perrucci and Perrucci, 2007). These changes include dissolving the iron-bound business bureaucracy and proliferating work that is unstable and without long-term careers and their benefits. Market competition eliminates personnel through the new technologies. Greater productivity results in using fewer workers (Sennett, 2006).

Concurrent with the New Economy is dissipation of the shared prosperity for American workers. Hedrick Smith holds that multiple enacted and adjudicated US policies favoring the ultra-rich retard economic growth, jobs, and remuneration for ordinary workers (Smith, 2012). Mollona notes that constructs and generalizations relating to 'post industrial' work do not entirely fit ethnographic observations in both industrial and developing countries. Overall, managerial policies for work conceptualized in Taylorism and Fordism persist; white-collar workers experience Braverman's deskilling and alienation, and class relations remain in various forms (Mollona, 2009a). At times, "The 'modern' system of flexible production is built upon a network of Victorian sweatshops hidden beneath the post-industrial façade of shopping malls, highways and leisure centers" (Mollona, 2009b: pp. xiii–xiv).

The End of Work?

The era of lifetime jobs gradually erodes, replaced by insecure 'contingent work,' including part-time, contracts and temporary persons – all are workers who are not full-time with full benefits. Conditions of employment not obtained by contingent workers include job training and career advancement with a firm. Such workers become employed only because of an immediate demand for them. Some people desire contingent work.

Rifkin (1995) and others pessimistically predict 'end-of-work' circumstances through technological and organizational rationalizations of work, including an irreversibly growing future unemployment and the loss of the centrality of work in peoples' lives. They foresee a crisis of lack of work in modern societies. Wilson (2012) and others optimistically counter this pessimism. Wilson holds that full employment with equality and a revitalized labor movement is possible given appropriate legislation and changes in corporate power. The issue is, how are these effected in the competitive global market and with neoliberal legislators fervent in many developed countries? Industrial policy cannot be free of values and norms. Accordingly, the future of modern work poses profound questions.

Abstract

This article discusses the emergence of the concept of the working class in Western Europe during the nineteenth century; the classical patterns of interpretation (structural, agency-focused, and combinations of these two approaches); the rise of 'peripheral' working classes, their historiography, and their conceptual implications; and the new insights offered by Third World historians for the analysis of advanced countries.

The Working Classes: Origins of the Concept

The concept of the working class emerged in Western Europe during the nineteenth century. Originally, the term was used as a plural, denoting a heterogeneous conglomerate of social groups performing various forms of wage labor. The working classes were considered to be a fraction of a larger 'proletariat,' that is, the estate of people without property, beyond honor. The wage earners were only a part of this amorphous mass. According to the French nobleman Granier de Cassagnac (1838: p. 30), the proletariat formed 'the lowest rank, the deepest stratum of society,' that consisted of four groups: 'the workers, the beggars, the thieves, and public women.' "The worker is a proletarian, because he works in order to live and earns a wage; the beggar is a proletarian, who does not want to work or cannot work, and begs in order to live; the thief is a proletarian, who does not want to work or beg, and, in order to make a living, steals; the prostitute is a proletarian, who neither wants to work, nor beg, nor steal, and, in order to live, sells her body." As capitalist relations crystallized more and more, the desire arose among the 'respectable' workers to distinguish themselves from the rest of the 'proletariat.'

Over the course of the nineteenth century, social theorists and the emerging labor movements began to redefine these notions: (1) the working classes became homogenized as a singular working class; (2) this working class was identified with the proletariat; and (3) this proletariat/working class was marked off in three ways: from the petty bourgeoisie, from the so-called lumpenproletariat (the criminal and unsteady 'dangerous classes'), and from the unfree workers (slaves and serfs). An early example of this development was the *Manifesto of the Communist Party* of 1848, which emphatically distanced the proletariat/working class on the one hand from the 'lower middle class, the small manufacturer, the shopkeeper, the artisan, the peasant,' and on the other hand from the "'dangerous class,' the social scum, that passively rotting mass thrown off by the lowest layers of old society" (Marx and Engels, 1973: p. 77). A similar sharp distinction was drawn between 'free' workers and the slaves in the South of the United States and in some colonies.

Moreover, the notion of a working class was a gendered abstraction, based on the assumption that workers' families exist mainly on the wages earned by the male head of the household and perhaps the additional income of other household members. From 1900 or so scholars of various theoretical orientations seemed to have reached an agreement on what a worker is. In 1926 the German social-christian sociologist. Briefs summarized this *communis opinio* as follows: "The worker is *personally free*, i.e., his physical and spiritual-moral powers are completely at his own disposal. […] He *has no property*, i.e., he has no exclusive material power over capital as a secure basis with relative permanency. […] He has neither a stock of consumer goods that enable him to live, nor permanent interests of capital. […] He lives in economic circumstances in which means of subsistence can be obtained only through *economic returns*. […] He is forced to offer personal capacities with an economic exchange value in return for means of subsistence" (Briefs, 1926: p. 149).

Origins in the 'Core Countries'

Detailed surveys of the living and working conditions of the working classes date from the first decades of the nineteenth century. A relatively early example was the Tableau de l'état moral et physique des ouvriers employés dans les manufactures de coton, de laine, et de la soie, written by Villermé (1840), a medical doctor with a great interest in the social and physical condition of 'the people.' Many writings of this kind were intended partly as moral and political indictments of social abuses. One of the best known instances is Engels's (1845) *Die Lage der arbeitenden Klasse in England* (*The Condition of the Working Class in England*), which gave a minute description of the working classes in English industry, mining, and agriculture. During the second half of the nineteenth century social surveys became a quite common genre, especially in industrializing Western Europe. Highlights include the many studies of Frédéric Le Play and his school which covered all of Europe, beginning with *Les ouvriers européens* (1855); Henry Mayhew's *London Labour and the London Poor* (1851–61) with the significant subtitle 'a cyclopaedia of the conditions and earnings of those that will work, those that cannot work, and those that will not work'; Charles Booth's *Life and Labour of the People of London* (1892–97); Alphons Thun's detailed monograph *Die Industrie am Niederrhein und ihre Arbeiter* (1879) on the industrial and working classes in West Germany; and numerous publications of the German Verein für Sozialpolitik (Social

Policy Association), including Max Weber's famous study of agricultural laborers in East Prussia (1894).

All these works were mainly contemporaneous, though they have by now themselves become important historical sources. Truly historical studies of working classes followed at the beginning of the twentieth century. A pathbreaking effort was the trilogy written by John Le Breton Hammond and his wife Barbara Bradby. *The Village Labourer, 1760–1832* (1911), *The Town Labourer, 1760–1832* (1917), and *The Skilled Labourer, 1760–1832* (1919). Together these studies provide a rich survey of the British working class during the Industrial Revolution. In other countries similarly wide-ranging works usually were published much later, generally after the World War II.

Classical Debates

The study of the working classes has always been central to social and labor history. But different aspects have been studied and emphasized.

The concept of the working class has been used in many different ways. Somewhat simplifying, one might distinguish three main patterns of interpretation. The structural approach uses the notion of the working class in a restrictive sense as a term merely characterizing the common socioeconomic location of a group of wage earners. The historical study of a particular working class then boils down to the reconstruction of their joint 'class position.' How this class position is analyzed depends on theoretical assumptions (Marxist, Weberian, or otherwise) and on the various ways in which research is operationalized (models of social stratification).

A second approach focuses on agency and emphasizes culture, mentalities, consciousness, and social and organizational behavior. Numerous variations on this theme have developed over time. Perhaps the most influential approach was presented by Edward P. Thompson in his *The Making of the English Working Class* (1963). Here, he argued that. "The notion of class entails the notion of historical relationship. Like any other relationship, it has a fluency which evades analysis if we attempt to stop it dead at any given moment and anatomize its structure." Class, according to Thompson is an outcome of collective experience, and workers are active participants in their own class formation.

While the first approach has been criticized for its 'objectivism' and the second approach for its 'culturalism,' a third approach considers working-class formation as 'an outcome of temporal conjunctures between multiple causal structures' (Sewell, 1990: p. 73). In this view, class formation results from a combination of economic and technological changes on the one hand and of cultural, political, and discursive developments on the other hand.

The debate on working-class formation is paralleled by an extensive debate on working-class devolution: Does it still make sense to speak of working classes in advanced capitalist countries? Or have these classes dissolved? And if there has been a process of devolution, how and when did it start? Naturally, everything depends again on one's conceptualization of the working class. What does one consider as decisive: structural issues (free wage labor, etc.), collective behavior (e.g., trade unions, strikes), or cultural features? Whichever position one takes, it is evident that the condition of wage earners in advanced societies has changed profoundly during the twentieth century. Research has not given equal attention to all these developments. Especially the cultural shifts after the World War II remain underexplored.

Most early contributions to working-class history focused on work, industrial relations, and labor markets. At a later stage the field of research was expanded and historians began to pay serious attention to other aspects of working-class existence, including labor processes, family life, religion, etc. Over the course of time the first approach has become more sophisticated and the second approach has gained influence. The historiography of the workers as a class is now increasingly merged with the historiography of race, ethnicity, and gender. While earlier historians considered race and gender as mere adjuncts of class, it is now generally becoming accepted that class, race, and gender are thoroughly interpenetrating, and that they shape each other. As a result of these developments, working-class history increasingly overlaps into women's studies, ethnic studies, anthropology, institutional economics, sociology, or social psychology.

Now that there exists a huge and still growing body of literature on the various historical aspects of working-class existence first attempts are made to integrate the history of various aspects of working-class life and to write comprehensive syntheses. The most spectacular example of such an endeavor is the ongoing project on the *History of the Workers and the Labor Movement in Germany since the End of the Eighteenth Century*, coordinated by Gerhard A. Ritter (see Kocka, 1990, 1991; Ritter and Tenfelde, 1992; Schneider, 1999; Winkler, 1984, 1985, 1987).

The Rise of the 'Periphery'

The growth of working classes outside the advanced capitalist countries has, especially since the World War II, caused an increased interest in the working classes of Africa, Asia, and Latin America. From a contemporary point of view this field was first explored by anthropologists and students of industrial relations, who were interested in the problems accompanying the integration of rural migrants into the emerging wage-earning economies. Early examples were A.L. Epstein's ethnographic *Politics in an Urban African Community* (1958), on copper miners in Northern Rhodesia, and industrial relations studies driven by the question how processes of social change could be controlled and how the 'commitment' of the workers could be intensified (e.g., Moore and Feldman, 1960; see also Breman, 1999).

Simultaneously, historiographical studies emerged; initially these were often based on official sources and looked at the workers through the eyes of employers and authorities. Such was for instance the case in J. Norman Parmer's thorough *Colonial Labor Policy and Administration* (1960) on the rubber plantation industry in Malaya during the last decades before the World War II. Since the 1960s and 1970s the historiography of the 'peripheral' working classes has changed too. First, there was an upsurge of classical labor movement history. Many of the major early studies of this genre were written by radical

intellectuals, like Jean Chesneaux's *Le mouvement ouvrier en Chine de 1919 à 1927* (1962) or Guillermo Lora's *Historia del movimiento obrero Boliviana* (1967–70). Second, gradually the perspective broadened and everyday life, mentalities, etc. of working classes received more attention, just as had been the case in the historiography of the high-income countries. Early attempts in this direction were still heavily influenced by Western models of historical development. Morris D. Morris's *The Emergence of an Industrial Labor Force in India: A Study of the Bombay Cotton Mills, 1854–1947* (1965) is a major example of this approach, despite its rich empirical basis. Later attempts often tried to develop a less Eurocentric approach. Pathbreaking works include Charles van Onselen's *Chibaro* (1976) on mine labor in Southern Rhodesia or Ranajit Das Gupta's *Labour and Working Class in Eastern India* (1994) on plantation workers, miners, and textile workers in Assam, Bengal, and elsewhere. These new developments have been covered by a series of consecutive collections of essays (Sandbrook and Cohen, 1975; Gutkind et al., 1978; Cohen et al., 1979; Munslow and Finch, 1984; Agier et al., 1987; Amin and Van der Linden, 1997). While the traditional historiography of the high-income countries focused primarily on artisanal and factory labor, the new working-class historiography of the peripheral countries reflected the peculiarities of colonial exploitation and unavoidably paid much attention to the labor in agriculture (including plantations), mining, and the transport sector (docks, railways).

Global Insights

The rise of working-class history in low-income and medium-income countries has made necessary a rethinking of old concepts. First, in the periphery, the larger part of the wage earners is not 'free' in an economic sense. According to the classic definition, wage earners, as 'free persons' are free in a double sense because they alone market their own labor as a commodity and have no other commodity for sale. A 'free' worker is, strictly speaking, someone without obligations to any particular employer. He or she can cancel employment at will and apply for a job with another employer. In reality, however, such a completely uncommitted relationship with the boss is rare, occurring, for example, among some forms of casual labor. Many workers are tied to their employer, for example, through debts or nonmaterial obligations. There can also be all sorts of cultural or geographic reasons why it is difficult to change employers. Somewhat better-placed personnel can be tied to a firm through superannuation provisions. Frequently, the accommodation of workers is part of the labor contract, etc. In short: what formally seems like a free labor relation is in practice often much less free. A 'free' worker, moreover, does not possess his or her own means of production at all. But in reality there are many types of labor relations in which the employee contributes at least part of the means of production himself. One thinks here of factory workers who own (part of) their own tools, but one can also think of agrarian share-cropping arrangements. Still clearer is the case of self-employed workers, who formally are wholly independent, but who in fact often form a very flexible labor force for enterprises. We can also mention here the case of home workers.

Second, there is wage labor integrated throughout in households and families whose survival always remains partly dependent on other activities. Not only does a great deal of subsistence labor take place every day in every family (especially, but not exclusively performed by women), but there are usually also several forms of activities remunerated with money. Already in the early 1970s Allen observed, for example: "Cash crops and wage employment are simply alternative methods of coping with the encroachment of capitalism on the traditional way of life. A fall in the demand for labour increases the emphasis on subsistence or cash-crop production, whereas a drought or a bad harvest, for instance, forces Africans to enter the labour market" (Allen, 1972: p. 181). Within these arrangements with multiple coping methods the 'roles' different family members have are often not fixed permanently, but instead signify a transient social relationship, which can be replaced rather quickly by other sources of income.

Third, the new working class does not mainly or exclusively exist in the industrial sector. The agricultural sphere is proportionally more important in this sphere rapidly advancing proletarianization has created a large stratum of agricultural laborers and share tenants.

Fourth, in the so-called Third World and even in the East- and Southeast Asian newly industrializing countries, permanent employment relationships have always been the exception rather than the rule. Insecure employment relationships, underemployment, and long-term unemployment are the reality there.

Implications for Future Research

The new insights offered by Third World historians have implications for the advanced countries as well.

First, the dividing line between wage labor and small entrepreneurship is much more obscure than was originally thought. In both the 'Third' and 'First' worlds there are gray zones of (ostensible) self-employment, in which individuals formally work on their own but in reality are dependent on one or two customers. This type of self-employment has been widespread in peripheral capitalism for decades, but lately, it has been increasing rapidly in the centers as well, such as in the construction business. Generally, there seems to be a historical connection in highly developed capitalism between phases of rising unemployment, on the one hand, and stagnation or the growth of 'small-scale' self-employment, on the other.

Second, the border between wage laborers and the marginal groups is not nearly as obvious as older theories would have us believe. In times of desperation, regularly employed wage earners may indeed exhibit behavior characteristic of the *Lumpenproletariat*, such as begging and prostitution, as a way to survive. They will also steal at the workplace, which represents thoroughly criminal behavior from the entrepreneurial viewpoint. Yet, the experience in the Third World has drawn our attention to a lower social class that can be characterized neither as the industrial reserve army in a Marxist sense nor as

the classic *Lumpenproletariat*. Inevitably we need to come up with a new concept to apply to insecure employment relationships in this respect.

Third, the concept of the 'free' laborer is less precise than is usually assumed. Fourth and last, the strict differentiation commonly made in advanced countries between urban and rural life must be revised. Contrary to what modernization theories like to tell us, the ties of urban migrants to their home villages often do not weaken but strengthen over time. Most likely, the reason for this is the lack of social insurance systems. Therefore, the villages become safety nets during times of economic crisis. Recently, though, many villages have not been able to fulfill this task, since the rise of a commodity economy has drained their capacity for subsistence.

What it means to be classified as 'working class' is changing; the category is becoming especially multifarious. We could even flip our intellectual problem and ask why a 'full-time proletarian' in capitalism should have existed or can now even exist at all. From the entrepreneurial standpoint, part-time proletarians are cheaper by far. Part-time proletarians (who belong to a household in which there are other sources of income, e.g., from agricultural work or from self-employment) lower the bottommost, barely acceptable wage threshold because they have other forms of real income (Wallerstein, 1983).

Abstract

Working conditions range from the employment relationship to the environment in which workers perform their tasks. This article addresses how working conditions are shaped by regulation. Most commonly, regulation establishes labor standards, that is, sets minima. Regulation can shape structures for negotiation that affect working conditions. Most narrowly, regulation is understood as emanating from government through laws as well as administrative rules. Social norms along with worker relative bargaining power also affect working conditions. Some see labor standards as a cost and/or as distorting labor markets; for others, standards reflect social norms and power relations between employers and workers.

Working conditions range from the terms under which workers enter the employment relationship to the environment in which they perform their tasks. This article addresses how working conditions are shaped by regulation. The most common purpose of the regulation of working conditions is to establish labor standards, that is, set minima for wage, hours, or health and safety conditions. Also, regulation can establish a framework for the formation of structures for negotiation that contribute to shaping working conditions. Most narrowly, regulation is understood as emanating from government through laws as well as administrative rules (executive). Courts help enforce laws. Also, the relative bargaining power of labor unions and other organizations affects the ability of workers to bargain for improvements, to obtain thorough enforcement, and to gain new rights through legislation. Lastly, social norms along with worker relative bargaining power are reflected in company personnel policies and these also affect working conditions. Some observers see labor standards as an externally imposed cost and/or as having a distorting effect on labor markets. Others see regulation as a reflection of social norms and of power relations between employers and workers. In this view, regulation may hinder, add costs to, or facilitate greater efficiency in production; its effects are not unidirectional. Three recent trends – the emergence of new employment arrangements, weakened enforcement, and the expansion of cross-national production – challenge the ability of national governments to regulate working conditions and require further research.

Historically, working conditions have varied widely across countries and across time within each country in terms of their quality – from the workers' vantage point. Working conditions have been subject to regulation to varied degrees, a situation that accounts for variability in their quality.

Working conditions are part of employment systems that have been shaped by actions, rules, and regulations emanating from several spheres of society. These include the legal, judiciary, administrative, and collective bargaining spheres as well as personnel policies and informal social norms. All these spheres shape the 'way of doing business' (Piore, 1990) as well as working conditions for workers. In industrialized societies, the regulation of working conditions has primarily affected people in waged or salaried employment, that is, those who are in a relationship, recognized legally as economically dependent, with an employer who usually controls the means of production. In recent years and in some countries, however, some labor regulations have been applied to the self-employed.

Working Conditions, Definition

Working conditions consist of the following elements:

1. *The terms of the employment relationship*. They include whether the employment relationship is durable or for short term, formal or informal. The terms of employment may be explicit or implicit.
2. *Access to employment*. This access may be equitable or discriminatory. In the latter case, groups of workers may be excluded from employment or have differential access based on their race/ethnicity, gender, age, or other characteristic.
3. *The workplace itself*. Work may be performed in a single site, multiple sites, or from the worker's home.
4. *The wage level*.
5. *Time at work and away from work*. This includes the daily, weekly, and yearly number of work hours as well as their scheduling. It also includes provisions for time away from work due to illness, vacation, or leave for family or medical reasons or for training.
6. *The supervisory structure and mechanisms*. This structure may or may not include procedures for due processes in disciplining, discharges, and layoffs. It may entail varied degrees of protection from supervisory arbitrariness.
7. *Health and safety conditions in the workplace*. These include occupational health, that is, the ways in which the performance of work tasks affects workers' physical health and well-being, and environmental health, that is, whether the work environment in which the work is performed has negative effects on physical health.
8. *Voice at work*. This encompasses access to worker representation and the shape of representation structures. These structures may include representative organizations such as

labor/trade unions or worker associations as well as participatory structures such as workplace councils.

9. *Social protection/social insurance benefits for the individual and their dependents that have been tied to waged employment and are administered through payroll systems.*

Some of the elements of working conditions listed above have a direct relationship to employment and the performance of work, e.g., health and safety conditions at work. Others have been historically tied to employment with a particular employer in the United States and to labor market participation in Western European countries but do not have to be. For example, health insurance coverage can also be provided as a universal benefit regardless of work activity.

Systems of Employment and Working Conditions across Countries

National systems of employment can be viewed as a whole that provides degrees of regulation and protection to workers and employers in a variety of ways (Jacoby, 1982; Boyer, 1986; Piore, 1986, 2010). Systems of employment can be seen as a conjunction of 'spheres'; they encompass legal, executive/administrative, judiciary, collective bargaining, and employer personnel policy 'spheres' as well as social norms and customs. Different countries have a varied mix of reliance on these spheres to affect working conditions. Some rely on collective bargaining approaches, whereas others favor the action of the legislative and executive spheres combined. The regulation of working conditions can therefore be achieved through these spheres in a different manner across countries as well as across time in one country.

The Purpose of Regulation on Working Conditions

The regulation of working conditions has several purposes. Most commonly, it establishes labor standards, that is, sets minima for wage, hours, or health and safety conditions that employers are mandated to respect and that are enforced through prohibition and penalties. This is the narrowest role of regulation.

Regulation can enable the formation of structures for negotiation, mediation, or problem solving that contribute to shaping working conditions in varied ways and with diverse outcomes across industrial sectors and occupations (Weiler, 1990). One example of such regulation is the federal and state statutes governing worker representation and collective bargaining (e.g., US National Labor Relations Act of 1935).

Sources of Regulation

Most narrowly and conventionally, regulation is understood as emanating from government (national, state, local) through laws and statutes (legislative branch), as well as administrative rules (executive). There is a range of enforcement philosophies and mechanisms across countries. For example, in the United States, separate agencies have been established over time to enforce different standards. The Wages and Hours Division in the US Department of Labor enforces the Fair Labor Standards Act of 1938 and related legislation on minimum wages and overtime pay for hourly workers, while the Occupational Health and Safety Act sets minima for safe working conditions. Through inspectors and administrative courts, violations are verified and penalties issued for responsible employers. In contrast, France and to some extent Marocco and Mexico rely on a professional body of labor inspectors to monitor and be the first level of assessment of a wide range of labor standards and health and safety conditions (Piore, 2010). Enforcement mechanisms and their effectiveness play a key role in the shaping of working conditions. Conversely, the work setting affects the effectiveness of enforcement. For example, if workplaces are small, scattered, and numerous, it is difficult for an enforcement agency that relies on visits by inspectors to monitor work conditions and enforce a specific law.

The court system is another feature of the regulation of working conditions. Courts contribute to enforcing existing laws and statutes. For example, an employer responsible for hazardous working conditions that have resulted in worker death may be sued. Sometimes, in response to cases initiated by workers, courts issue decisions in areas where government legislation and executive enforcement have not acted yet. In this case, court actions precede legislative action. A number of countries (e.g., France, Germany) rely on peer representation labor courts (employer, worker/union representatives), which address labor enforcement issues that cannot be mediated by labor inspectors. These courts rely on a mix of mediation and adjudication processes.

Working conditions are also affected by the relative bargaining power of workers and their organizations. In turn, this bargaining power is shaped partly by the provisions made in legislation for worker voice and representation. For example, the US National Labor Relations Act of 1935 established a mechanism for representation for many workers in the post–World War II years and also shaped the form that labor unions took. In some European countries, where there is administrative extension of terms of a collective agreement to whole sectors, workers are directly affected by conditions in union collective agreements with leading firms. The relative bargaining power of labor unions and worker organizations affects the ability of workers to bargain for improvements, the thoroughness of enforcement of existing laws, and the ability to obtain new laws.

Lastly, social norms and customs along with worker relative bargaining power are reflected in personnel policies and employer practices; these also affect working conditions. In countries with a limited role for government regulation and with low incidence of collective bargaining, such as the United States, many aspects of working conditions are shaped by personnel policy rather than law or collective bargaining and thus vary greatly across employers.

In sum, working conditions are shaped by the totality of action in these respective spheres and by the interaction of actions from these spheres. For example, in the United States, provisions in collective bargaining agreements or innovative personnel policies may serve as a model for later state or federal legislation. In France, national sectoral bargaining in lead industrial sectors on a particular aspect of working conditions often precedes national legislation. (National

sectoral bargaining occurs between large employers and their federations, on the one hand, and national unions and their federations, on the other hand, and is sometimes mediated by government.) In some countries, national sectoral bargaining on a particular issue (e.g., implementing shift work) is used sometimes as an alternative to government regulation.

The Long-Standing Debate on the Regulation of Working Conditions

The role and benefits of the regulation of working conditions has been the subject of long-standing debate. One view sees regulation, particularly regulation on labor standards, as an externally imposed cost and/or as having a distorting effect on the operation of labor markets. This view stems from the neoclassical school of economics whose core perspective – presented here in stylized fashion – is that markets are self-regulating and that prices must be allowed to vary freely in order to be efficient allocators of human and capital resources. This view also tends to assume that there is no significant conflict or power differential between workers as a group and employers as a group. Rather, workers and employers are individual decision makers who make choices unhampered by power differentials. Critics of minimum wage laws have argued that the laws push wages above the 'market clearing' level and thus cause unemployment. Other analysts have taken a more benign view of their impacts on firm decisions and employment levels. The research literature has centered on the empirical measurement of the relative magnitude of effects on employer costs and employment levels (Dube et al., 2010; Houseman, 1998).

Another view sees the regulation of working conditions and its effects as a special case in economic analysis because labor markets are deemed the least self-regulating among all markets. In this view, the regulation of labor markets cannot easily be analyzed with the conventional tools of economic analysis.

Consistent with this view, another perspective sees regulation as a reflection of customs and social norms and of power relations between employers and workers – all of which vary across countries (Piore, 1986; Gautié and Schmitt, 2010). In this view, regulation may hinder, add costs to, or facilitate greater efficiency in production; the effects of the regulation of working conditions are not conceived as unidirectional. They are expected to vary widely depending on the contents of regulation, the structure of particular industries, and their production organization. For example, minimal labor standard on wages, hours, or health and safety have been argued to discourage 'sweatshops' and favor other business strategies that are less onerous to workers (Piore, 1990). In sweatshops, workers are unprotected because employers are insulated from the economic impact of variations in productivity among workers and over time thanks to the piece rate system (workers are paid for measurable units of output). A minimum wage rate that is high enough to create employer concern with productivity may compel a change in a firm's practice and working conditions; it may deter the use of low-productivity workers such as young children.

Recent debates on the regulation of working conditions in North America and parts of Europe have been colored by the general policy trend toward deregulation of markets. Laws on hours and scheduling, and those on worker representation structures, have been questioned. Advocates of deregulation have argued that existing regulations fit an old order of production organization, and market structure, and must be removed. Others have called for their replacement with different standards and representation systems that provide equivalent protections for workers but through new means that are more appropriate for contemporary forms of production and work organization.

Recent Trends and Implications

Diversified Employment Arrangements

In the post–World War II period, the contents and enforcement of the regulation of working conditions in late industrialized countries have been constructed, albeit in different ways, around a certain notion of the employment relationship as a relatively long-term, stable attachment to a single employer with the work tasks being performed on the employer's work site. While there were always exceptions to this notion – for example, farm labor, construction, expert consulting, or domestic labor – the bulk of postwar regulatory attention to working conditions has been structured around this employment arrangement.

In the future, most observers expect less employer commitment to long-term employment relationships, less worker attachment to particular employers, and greater lateral mobility (across firms, industries, and possibly occupation). This is due to changes in the organization of production and employment structures within firms; increasingly, firms recruit workers from the outside labor market rather than relying on internal training and promotion. Career paths for workers will become less predictable and may span several companies and industries (Arthur and Rousseau, 1996; Cappelli et al., 1997).

The manifestations of these transformations include the emergence and establishment of varied forms of employment that are explicitly short term (limited-duration hiring, temporary work), may be brokered by an intermediary (a for-profit or nonprofit temporary/staffing service), or may be the result of contracting arrangements between two businesses (e.g., workforce of a janitorial subcontractor), thus creating a triangulated employment relationship. Independent contracting has also become more common – a situation where individual workers are treated as self-employed under the law, that is, not wage/salary employees, while they are economically dependent on a relationship with a sole purchaser of their services.

Short-term employment relationships may render existing regulations and their enforcement ineffective; workers may not stay long enough in a particular job to bring a complaint about a violation of a labor standard. Triangulated employment relationships entail ambiguities as to employer responsibility for compliance with particular laws. Independent contracting means that there is no employment relationship and therefore no option for regulation under most labor and employment law, leaving solely collective organization for bargaining and mobilization for policy advocacy as alternative venues for

affecting working conditions. In practice, the financing and implementation of social protection benefits such as health insurance and pension through employment relationships are weakened and, in countries with employer-based systems, rendered ineffectual.

As employment relationships change in these ways, the contents and means of the regulation of working conditions will likely change. The regulation of working conditions will require a reconceptualization and analysis.

Although employment relationships change in these ways, they still remain the primary means through which core social protection benefits continue to be provided. For example, in the United States, which has relied on social protection benefits being provided by employers either voluntarily (fostered by tax deduction incentives) or through rare mandates, regulatory attention has focused on mechanisms to better enable workers to meet their care responsibilities. For example, family leave – time off for caring for a child or sick relative – has been the subject of US legislation (1993), of continued activism at the state and federal level, and of innovative benefit policies by some large employers.

Enforcement of Regulation

Observers have also noted that related changes in the organization of production and firm practices have changed the context for enforcement of legal statutes on working conditions, thereby restricting reliance on legal mechanisms of regulation. The production of goods and services through networks of firms with varied ownership structure and a diversity of interfirm relationships (alliance, franchise, subsidiary, subcontracting) has created labor environments where workers experience difficulty knowing how to exert their statutory rights, and traditional enforcement mechanisms are less effective (Weil, 2010). Developed countries have witnessed difficulties with standards enforcement. Notably in the United States, rates of violation of wage and hours laws, of workers' compensation, or health and safety rules have been high in several industries in a number of urban markets (e.g., restaurants, retail, delivery services, garments (Theodore et al., 2012)). Enforcement challenges have led scholarship to explore models of enforcement, contrasting administrative enforcement of single statutes (e.g., US system) to the interpretation and enforcement of labor standards as a whole through a professional corps of inspectors such as in France, Morocco, or the Dominican Republic (Piore, 2010).

The Regulation of Working Conditions and Globalization of Production

International economic integration has continued to grow in recent years. Its main features include the reduction or removal of trade tariffs and of restrictions on capital flows either by policy change or simply through the spread of new communication technologies, which put distant production areas directly in competition. It has resulted in greater cross-border capital mobility, the freer movement of goods, and the development of production processes ('production chains') that span national boundaries. This pattern holds particularly for manufacturing and, increasingly, for service activities such as call centers or records transcription (Batt et al., 2009; Whitman, 1999).

In this context, the issue of the regulation of working conditions will take on new facets requiring further consideration and research. First, the adaptation and strategic responses of firms in industrialized countries to minimal labor standards were developed during the post–World War II period when mass production was in expansion, and domestic markets were relatively sheltered from foreign competition. Growing competition from goods and services produced in countries with dramatically lower wages and fewer regulations of working conditions (e.g., Bangladesh, Cambodia), as well as the increased opportunities for firms to expand their production processes cross-nationally, are continuing to change the parameters that affect working conditions for workers in both industrialized and developing countries. These developments challenge the ability of national and local governments to regulate working conditions in ways that ensure effective enforcement.

Second, in developing countries, the growth of activities linked to the production processes of cross-national firms has given rise to extensive subcontracting production networks where monitoring is difficult. It has also favored the extension of forms of employment (e.g., off-site contract labor such as home-based light assembly) that are not subject to existing national regulation of working conditions, or that take place in settings and on terms in which monitoring and enforcement are difficult (see research on 'informal employment').

Additionally, the ability of countries to enforce the regulation of working conditions through labor standards in those developing countries with low wages and low-quality working conditions is weakened by the ability of cross-national firms to shift production to another low-wage country with a workforce of similar skill level. Over the past decade, very large, visible, multinational corporations have addressed the issue of labor standards enforcement in their long, diverse, subcontractor chains through voluntary codes of conduct and 'ethical trade' certifications, including monitoring by the corporation, nongovernmental organizations, or other recognized third party (Locke et al., 2007 for a review). The degree and quality of labor standards enforcement achieved through these mechanisms varies greatly, depending not only on investment in monitoring but also on the productive quality of the component firms of the production network. Going forward, some multinational corporations are exploring other approaches directly focused on how the production process itself (work organization and technology use) generates poor working conditions (Locke et al., 2007).

Outlook and Future Research Issues

These trends raise several concerns. For workers, there is increasing risk of worsening working conditions, that is, increased difficulty with accessing jobs subject to the full extent of regulations and lower odds of benefiting from thorough enforcement of their rights and protections at work. The quality of employment is likely to decline – if policy thinking and national regulatory approaches do not adapt to these changes.

Three groups of issues will need to be considered in future research. First, the parameters of firms' choices will need to be documented in the context of particular countries and for specific activities, contrasting capital-intensive and labor-intensive manufacturing as well as comparing service activities among themselves.

Second, future research on regulation will increasingly examine the sphere of international organizations (e.g., World Trade Organization, Organization for Economic Cooperation and Development, International Labor Organization, European Union), the process of international negotiation of international conventions on working conditions, and the impacts of these conventions, first, on national regulation efforts and, second, on firm strategies and practices. Research has developed and will continue to explore ways to achieve implementation of labor standards that are adaptable to national institutional and social settings as well as specific industry contexts. This research is relevant to working conditions in developed as well as developing economies.

Lastly, for policy analysis and discussion, the core question will be what *should* be the complex of regulation of working conditions that is most compatible with new forms of cross-national production, the productive use of new production and communication technologies, and the well-being of workers in industrialized and developing countries.

Abstract

Working memory, which refers to the temporary storage of recently perceived and interpreted information for further processing and cognitive manipulation, depends on distributed neural systems involving multiple brain regions that include several prefrontal and higher-order temporal and parietal cortical areas. There is considerable evidence that the temporary storage of information depends primarily on modality-specific and multisensory temporal and parietal cortical areas. Distinct prefrontal areas in interaction with these posterior storage areas support various aspects of control processes such as the monitoring of the contents of working memory (known as the epoptic process), rule-based attentional selection, active-controlled retrieval, inhibitory control, etc. The mid-dorsolateral prefrontal region, which underlies the monitoring of the contents of working memory, in interaction with certain areas of the posterior parietal cortex, forms a fronto-parietal circuit for the manipulation of information in working memory.

The present article focuses on research that aims to identify the role of various areas of the cerebral cortex in what has been termed 'working memory' at the cognitive level of analysis. In experimental psychology, the term 'working memory' has been used to refer to the temporary storage of information that is necessary for cognitive processing underlying the comprehension and learning of new information, reasoning, mental arithmetic, the mental manipulation of information, etc. This theoretical construct emerged in the 1970s out of earlier experimental behavioral work on short-term memory (see Baddeley, 1986, 2007), although the term 'working memory' was used as early as 1960 by Pribram, Miller, and Galanter in an attempt to deal with cognitive processing related to the planning of action. The term working memory has been defined variously to refer not only to the transient maintenance of information (short-term memory), but also to the further processing, including manipulation, of that information. For instance, one of the most popular working memory models in cognitive psychology assumes the existence of a central executive system supplemented by 'slave' systems that are specialized for the maintenance and processing of verbal, visuospatial, and episodic information (Baddeley, 1986, 2007). Such an expanded concept of a working memory system becomes almost tantamount to the online processing of information that occupies current awareness. Naturally, any system defined so broadly will be the result of neural processing across multiple areas of the brain. Investigations of working memory impairments in human patients with relatively restricted brain damage and in monkeys with precise excisions of specific cortical areas have begun uncovering some of the key cortical structures involved in working memory. It has been shown that modality-specific impairments in the temporary storage and processing of incoming and recalled information result from damage to particular cortical areas in the temporal and parietal lobes. Impairments on working memory tasks after lesions to prefrontal cortical areas are considered to reflect deficits in executive processing that is necessary to allocate attention to different types of information, inhibitory control, and to monitor the contents of working memory, the latter process also referred to as epoptic processing (Petrides, 2013).

The Prefrontal Cortex and Working Memory

There is considerable evidence that the prefrontal cortex plays a major role in working memory. The prefrontal cortical region, which lies anterior to the motor/premotor frontal cortex, has expanded enormously in the human and nonhuman primate brains and comprises many distinct areas that differ in terms of their cytoarchitecture (i.e., cellular composition) and their connections with other parts of the brain (**Figure 1**; Petrides, 2005). These anatomical facts imply that there must be differences in the local neuronal computations occurring within these areas since both the local circuitry, reflected in cytoarchitectonic structure, and their connections with other brain areas are distinct. The first evidence that the prefrontal cortex plays a major role in working memory came from research in the 1930s by Jacobsen and coworkers, who examined the performance of monkeys with lesions restricted to the prefrontal cortex on the delayed response task (Jacobsen, 1936). This work showed that frontal cortical damage rendered animals incapable of performing the delayed response task which was introduced by Hunter in 1913 to study transient memory in animals. This task typically is conducted in the following manner. The experimenter attracts the monkey's attention and, in full view of the animal, a reward (e.g., a piece of food) is placed under one of two identical stimuli (e.g., cups, plaques, etc.). The stimuli are then hidden from the animal's view by an opaque screen and, after a delay of a few seconds, the screen is raised and the animal is allowed to choose one of the two stimuli to obtain the reward if, of course, the choice is correct (**Figure 2**). In interpreting the impairment on delayed response in monkeys with frontal cortical damage, Jacobsen (1936: p. 52) argued that the behavior of such animals "instead of being directed by a balance of immediate, recent and temporally remote stimulation, is dominated by present external stimuli and the stable habit systems derived from earlier training; the mnemonic influence of past experience is lacking."

The demonstration that adequate performance of the delayed response and related tasks is impaired severely by lesions of the prefrontal cortex has been the starting point of several investigations into its possible role in working memory.

Figure 1 Cytoarchitectonic maps of the prefrontal cortex on the lateral surface of the human and the macaque monkey brains by Petrides and Pandya (see Petrides, 2005). Note that the white region in front of the central sulcus represents the motor (area 4) and premotor (area 6) cortex. Several prefrontal cortical areas can be defined based on differences in cellular architecture. Note that the cortex within and surrounding the sulcus principalis (see arrow) is often referred to as area 46 in the older literature (e.g., Goldman-Rakic, 1996), but Petrides and Pandya have subdivided old area 46 into area 46 proper (yellow) and related areas 9/46d and 9/46v (green) based on comparative cytoarchitectonic analysis of human and macaque monkey prefrontal cortex. as, arcuate sulcus; cs, central sulcus; sfs, superior frontal sulcus; sp, sulcus principalis, also known as principal sulcus (arrow); sprs, superior precentral sulcus.

The lesion investigated by Jacobsen involved the entire prefrontal cortex. Subsequent research on monkeys by Mishkin, Pribram, Gross, Weiskrantz, and others has demonstrated that (1) lesions restricted to the lateral surface of the prefrontal cortex impair delayed response performance, (2) the delay is critical for the impairment to emerge, and (3) the impairment on the classical spatial version of the delayed response task can be localized around the sulcus principalis, a prominent sulcus that runs longitudinally in the middle of the lateral frontal cortex of the monkey and where area 46 lies (see Petrides, 1994, for review of this literature and illustrations of the experimental paradigms used). Note that, in the older literature, the definition of area 46 in the monkey includes area 46 proper and related area 9/46 as more recently defined by Petrides and Pandya on the basis of comparative cytoarchitectonic analysis (**Figure 1**). Thus, in older and some recent lesion and recording studies, area 46 is used to refer to both areas 46 and 9/46.

By the early 1970s, the method of recording the activity of isolated neurons in monkeys as they perform various cognitive tasks was perfected and a number of studies appeared that recorded the activity of single neurons in the prefrontal cortex during delayed response performance. Fuster and Alexander (1971) in the United States and Kubota and Niki (1971) in Japan were the first to record such neuronal activity and demonstrated that certain neurons in the lateral prefrontal cortex respond specifically when a particular location is indicated as the one to be remembered and continue to discharge during the delay period until the choice has been made. This early work and several later studies by Goldman-Rakic, Miller, and coworkers clearly established the existence within the prefrontal cortex of sustained neuronal activity during the delay period of various working memory tasks (see Fuster, 2008, for review).

Figure 2 In full view of the monkey, one of two foodwells, selected randomly, is baited with a reward (a) and then the two foodwells are covered by two identical stimuli (here square white plaques). (b) An opaque screen is lowered and, after a short delay, the screen is raised to allow the monkey to uncover one of the two plaques to find the reward. Uncovering the foodwell where the reward had been placed before the foodwells were covered and the delay imposed provides the monkey with a reward. Damage to the region of the sulcus principalis (see **Figure 1**, arrow) results in a severe impairment on this task. In the older literature, this impairment was interpreted as a location memory impairment resulting from damage to the cortex of the sulcus principalis (area 46). However, Petrides (1994, 2005) has shown that the problem arises from the requirement to keep track (i.e., monitor) the constantly changing location of the stimuli and that the impairment is not restricted to spatial stimuli, but is a general monitoring impairment in working memory that involves both spatial and nonspatial stimuli.

Thus, both the lesion and the single-neuron research indicated the involvement of the prefrontal cortex in some aspect of working memory. But what exactly is the role of the prefrontal cortex in working memory? In one of the major theoretical interpretations of the above data, Goldman-Rakic (1996) assumed that the prefrontal cortex is a critical region for the short-term maintenance of processed information and considered the different prefrontal cortical areas as specialized working memory modules for the maintenance of different types of information for the purpose of future action. For instance, it was argued that the dorsolateral prefrontal area 46 (i.e., areas 46 and 9/46 in the newer definition; **Figure 1**) is specialized for spatial working memory (i.e., the maintenance of location-related information), whereas the ventrolateral prefrontal area 45 is a specialized module for nonspatial visual working memory (i.e., the maintenance of object-related information; Goldman-Rakic, 1996). An alternative theoretical model of the role of the different lateral prefrontal cortical areas in working memory was proposed by Petrides (1994, 1996), based on research that further analyzed the nature of the impairment on various working memory tasks by human patients and monkeys with prefrontal lesions. Petrides argued that the existence of delay neurons in the prefrontal cortex, although implying that some neuronal computations are occurring there during the delay in working memory tasks, does not require the conclusion that the primary role of the prefrontal cortical areas is the short-term maintenance of information. For instance, neurons with sustained activity during the delay in working memory tasks can be observed in virtually every part of the cerebral cortex, as well as in several subcortical structures (see Fuster, 2008, for review). In addition, there was the major puzzle that patients with damage to the lateral prefrontal cortical region can perform well on many standard short-term memory tests such as simple recognition of recently experienced stimuli, digit span, and immediate story recall. Petrides was able to demonstrate that patients with lesions that invaded the mid-dorsolateral prefrontal region (areas 46 and 9/46) and monkeys with lesions restricted to this particular part of the prefrontal cortex are impaired on working memory tasks in which successful performance cannot be based simply on the maintenance of information in short-term memory but requires, in addition, the executive process of monitoring that information (the epoptic process). In one of these tasks, the self-ordered working memory task, the subjects are presented with different arrangements of the same set of stimuli and, on each trial, they have to select a different stimulus until all have been selected once (**Figure 3**). Since the same stimuli are constantly recurring in the same context, there are no differences in the familiarity or the contextual occurrence of the stimuli that often support memory performance and, therefore, successful performance requires the subjects to monitor closely (keep track of) those stimuli that have already been selected and differentiate them from the constantly recurring and equally familiar stimuli that have not yet been selected. Several experiments have shown that, if familiarity or contextual cues are available to support working memory performance, patients and monkeys with mid-dorsolateral prefrontal lesions (areas 46 and 9/46) can perform normally (see Petrides, 1994, 1996). Similarly, if the monitoring requirements are minimal and memory performance is taxed by increases in delay, monkeys with area 46 and 9/46 lesions perform normally. In other words, impairments after area 46 and 9/46 lesions appear when events in working memory (e.g., the choices made by the subject in a particular task) must be monitored closely. Importantly, the deficit in the monitoring of events in working memory after lesions to areas 46 and 9/46 was not restricted to spatial information but was observed in nonspatial working memory tasks requiring the monitoring of object information (Petrides, 1994, 1996, 2013).

Figure 3 In this self-ordered pointing working memory task, the patient has to select one of the designs that appear on the card, turn over to the next card on which the same designs will appear but in different positions and select one of the designs that he/she had not previously selected, and so on. Importantly, the same designs appear on each card but in random arrangements. Thus, there are no differences in the familiarity or the contextual occurrence of the stimuli to support memory performance. Since the same, equally familiar designs appear all the time and in the same context, the patient can only perform well by keeping a mental record of the designs that he/she has already selected and differentiate them from the equally familiar designs that remain to be selected. This monitoring process (also known as the epoptic process) has been shown to depend on the mid-dorsolateral prefrontal cortex (areas 46 and 9/46) in human patient and macaque monkey lesion research and in functional neuroimaging studies with normal human subjects (see Petrides, 1996, 2005, 2013, for review).

Further evidence for the importance of the mid-dorsolateral prefrontal cortex to the monitoring of information within working memory is provided by functional neuroimaging studies on normal human subjects that have consistently

shown increased activity in the mid-dorsolateral prefrontal region (areas 46 and 9/46) when the monitoring requirements in working memory tasks are high, regardless of whether the stimulus material is spatial or nonspatial (see Petrides, 1996, 2013). When the monitoring requirements (e.g., keeping track of choices across trials) in working memory tasks are minimized, activity is not observed in the mid-dorsolateral prefrontal region, but in other parts of the prefrontal cortex depending on the nature of the control process being tapped. For instance, in a study by Courtney et al. (1998) in which monitoring and manipulation requirements in working memory were minimal, activity related to the mnemonic maintenance of spatial information was observed in the caudal superior frontal sulcus (sfs) close to its intersection with the superior precentral sulcus (sprs) where the frontal eye field lies (see **Figure 1** for location of sfs and sprs). The location-related memory activity was found to be immediately anterior to the frontal eye field (most probably in area 6). This finding is consistent with the conclusion of Petrides (1994, 1996) that simple spatial short-term memory is not the primary role of the mid-dorsolateral prefrontal region (areas 46 and 9/46) which is involved in monitoring the constantly changing status of multiple events in working memory, i.e. the contents of current awareness working memory (the epoptic process) for both spatial and nonspatial information. It is also consistent with the suggestion from several previous studies that posterior dorsolateral frontal cortex, where Courtney and colleagues observed increased activity during the delay in a simple spatial short-term memory task, plays a critical role in the top-down regulation of spatial attention both in the presence and in the absence of the spatial stimuli and, as such, particular parts of it can be expected to contribute to the maintenance of location-related information through top-down focusing of attention during a delay (Petrides, 1996, 2005). In other studies of attentional selection of visual stimuli in which monitoring and manipulation requirements were minimized, activity increases were observed again in posterior dorsolateral frontal areas (e.g., Petrides et al., 1993; Bledowski et al., 2009).

The Temporal and Parietal Cortex and Working Memory

Several studies on patients who had sustained lesions limited to posterior cortical regions have documented impairments in short-term memory, thus providing evidence that the temporary maintenance of information may be occurring in particular temporal and parietal cortical regions (see Vallar and Shallice, 1990). For instance, there are several reports of patients with a selective impairment in auditory–verbal short-term memory after lesions to the inferior parietal region of the language-dominant left hemisphere. These patients may be able to maintain and repeat single numbers, letters, or words presented auditorily, but their span (i.e., the number of items that they can maintain after a single presentation) is severely limited (e.g., Warrington and Shallice, 1969). Later on, with the emergence of functional neuroimaging, strong evidence was provided that the anterior part of the inferior parietal lobule, the supramarginal gyrus, is a critical cortical region for the phonological aspects of working memory (Paulesu et al., 1993; Church et al., 2011). For instance, in the fMRI study of reading by Church et al. (2011) in which the length of words and lexicality were manipulated, activity in the supramarginal region of the language-dominant left hemisphere was consistent with increased phonological processing. Interestingly, it was the posterior part of the supramarginal gyrus (area PFG) which was showing modulation of its activity in relation to phonological processing, namely the part that is known to be most strongly connected with area 44 (Broca's region) in the inferior frontal region (e.g., Margulies and Petrides, 2013). Thus, there is now strong evidence that the left supramarginal gyrus in interaction with ventrolateral prefrontal area 44 may underlie the phonological loop in working memory.

Patients with severely impaired short-term memory spans for visual–verbal material usually have lesions in the occipito-temporal region of the left hemisphere (e.g., Shallice and Saffran, 1986). De Renzi et al. (1977) have investigated visuospatial span using the Corsi blocks test. In this test, the patient observes the examiner tap, in sequence, a number of randomly arranged blocks and has to reproduce this sequence. Patients with right posterior hemisphere lesions were particularly impaired on this task, suggesting that the occipito-parietal cortex in the right hemisphere may be critical for the maintenance of visuospatial information (De Renzi et al., 1977). More recently, Della Sala and Logie (2002) have provided evidence from patients with brain damage that visuospatial and object working memory can be dissociated, a finding that is consistent with the demonstration of two separate streams of visual information processing, an occipito-temporal stream for visual object information and an occipito-parietal stream for spatial and action processing (Ungerleider and Mishkin, 1982; Goodale and Milner, 1992).

The notion that posterior parietal and lateral and ventral temporal cortical regions may play a role in the maintenance of information in working memory receives additional support from work in nonhuman primates. For instance, there is considerable evidence that the anterior part of the inferior temporal cortical region, which is known to be the final stage in the occipito-temporal neural system underlying visual object perception, is also critically involved in short-term visual memory. This evidence comes both from investigations of the effects of lesions (Mishkin, 1982) and from studies in which the activity of single neurons was recorded in monkeys as they performed visual short-term memory tasks (e.g., Fuster and Jervey, 1982; Miller et al., 1991). Indeed, a lesion study in the macaque monkey dissociated the contribution of the anterior inferotemporal region from that of the mid-dorsolateral prefrontal region (46 and 9/46) in visual object working memory (Petrides, 2000). Increasing the delay during which information had to be maintained in visual working memory (while keeping the monitoring requirements minimal) impaired performance in monkeys who had lesions to the anterior inferotemporal region, but not in those with lesions to the mid-dorsolateral prefrontal region. By contrast, increasing the number of stimuli that had to be monitored (while keeping the delay minimal) produced an impairment after mid-dorsolateral prefrontal lesions, but not after anterior inferotemporal lesions. This double dissociation between the effects of these two lesions on the same visual object working

memory task provides the strongest possible evidence of the selective contribution of these areas in working memory (Petrides, 2000). In addition, lesions restricted to certain parts of the superior temporal cortex in the monkey have been shown to lead to a serious impairment in auditory short-term memory (e.g., Colombo et al., 1990). Thus, selective impairments in the maintenance of information can be obtained from damage to specific parts of the lateral and ventral temporal and posterior parietal association cortical regions: Auditory impairments after superior temporal cortical lesions, visual object impairments after inferior temporal cortical regions, visuospatial impairments after occipito-parietal lesions, phonological impairments after language-dominant inferior parietal lesions, etc.

Prefrontal, Temporal, and Parietal Cortical Interactions for Working Memory

How can the evidence for impairments in working memory from posterior parietal and temporal association cortical regions, as well as from lateral prefrontal cortex, be conceptualized? In the theoretical model proposed by Petrides in 1994, neural activity in higher-order temporal and parietal cortical areas underlies not only perceptual processing and long-term storage of information but also short-term maintenance of recently processed information which has been provided by the environment and/or recalled (i.e., reactivated) from long-term storage (**Figure 4**). The temporary storage of information is viewed as an integral part of neuronal computation in modality-specific and multimodal temporal and posterior parietal cortical regions, i.e., particular areas that are parts of auditory, visual, tactile, spatial, vestibular, kinesthetic, multisensory and, in the human brain, verbal (i.e. phonological, lexical, and semantic) processing streams (Petrides, 1994, 1996, 2013). On the other hand, the prefrontal cortical areas are considered to play a role in working memory as distinct executive processing modules that allocate attention to different types of information and monitor the contents of information in these posterior cortical regions. Thus, working memory can be viewed as the multicomponent workspace of current cognitive activity, i.e., the processing and manipulation of information that occupies current awareness, and is based on local computations occurring within specialized posterior cortical regions for the online maintenance and processing of specific information in interaction with different prefrontal cortical regions that contribute various aspects of executive processing. The posterior lateral frontal region (such as area 8 and rostral premotor cortex) regulates the attentional focus and selection of stimuli, the ventrolateral prefrontal region (areas 45 and 47/12) underlies the active controlled retrieval of information, and the mid-dorsolateral prefrontal region (areas 46 and 9/46) monitors the contents of working memory, a process referred to as the epoptic process (Petrides, 1994, 1996, 2013).

Several investigators studying patients with brain damage have explored the special contributions of the various prefrontal regions in the executive control of cognitive processing (e.g., Robbins, 1996; Shallice, 2002; Stuss and Alexander, 2007; Petrides, 2013) and, although these explorations may not have always been in the context of working memory, the specific executive contributions of the various prefrontal areas demonstrated are likely to be reflected in working memory processing, depending on the requirements of the task, the strategy utilized by the subjects, etc. The same applies to functional neuroimaging studies of working memory (see next section).

A Fronto-Parietal Circuit for the Manipulation of Information in Working Memory

The mid-dorsolateral prefrontal region (areas 46 and 9/46; **Figures 1** and **4**) is strongly linked with the cortex of the inferior parietal lobule and the nearby intraparietal sulcal cortex, consistent with the fact that concomitant increases in activity within the mid-dorsolateral prefrontal cortex and the posterior parietal cortex are often observed in many functional neuroimaging studies of working memory. In the theoretical model of Goldman-Rakic (1996), the connections of the posterior parietal cortex with area 46 are viewed as the neuroanatomical substrate of the provision of spatial input to a prefrontal area specialized for the maintenance of spatial information in working memory. In the model of Petrides (1994, 1996, 2013), these parieto-frontal connections are viewed as not only bringing spatial information but primarily providing the means by which areas 46 and 9/46, a specific prefrontal region monitoring the contents of working memory (epoptic processing), can interact with critical components of the posterior parietal region for the cognitive manipulation of information. In other words, in the Petrides model, the parieto-frontal interactions are viewed as the basis of the mental manipulation of information in working memory. Evidence has recently been provided for such a fronto-parietal circuit for the mental manipulation of stimuli in working memory (see Petrides, 2013 for review). For instance, in an event-related fMRI experiment, Champod and Petrides (2007) were able to show that the posterior parietal cortex is involved in the manipulation (operationally defined as the mental rearrangement) of information in working memory, whereas the mid-dorsolateral prefrontal cortex monitors the information that is being manipulated. Thus, there is critical interaction between the mid-dorsolateral prefrontal cortex and certain parts of the posterior parietal cortex during the manipulation of information, as one would expect since the current status of information in working memory is constantly changing as the information is being manipulated. More recently, neuropsychological evidence has been provided that lesions to the posterior parietal region can produce impairments on tests involving the manipulation and rearrangement of information in working memory, but not on working memory tests requiring only rehearsal and retrieval processes or long-term memory (Koenigs et al., 2009). Although the lesions in the latter study were focused on the superior parietal region, lesions in patients inevitably damage nearby areas (e.g., intraparietal sulcal cortex) and therefore, the exact posterior parietal areas contributing to the mental manipulation of information require further definition.

Sometimes the difference in the theoretical positions of Goldman-Rakic (1996) and Petrides (1994, 1996) is incorrectly framed in terms of domain-specific versus domain-nonspecific

Figure 4 Schematic diagram of the model of the neural basis of working memory proposed by Petrides (1994) and which provides a framework to conceptualize the available experimental findings. Specialized areas in posterior parietal and temporal cortex that are part of somatosensory/somatomotor (S), spatial (SP), auditory (A), visual object (V), or multisensory (M) processing streams are critical for the short-term maintenance of processed information. In the language-dominant hemisphere of the human brain, there are additional specialized somatomotor verbal, auditory verbal, and visual verbal processing areas that underlie phonological and other language-related working memory processing (not shown in the schematic diagram above). Interactions with the mid-ventrolateral prefrontal region (MVL) permit active controlled retrieval of information from posterior cortical areas and interactions with mid-dorsolateral prefrontal (MDL) cortex permit the monitoring of information in working memory. Furthermore, interactions of certain frontal areas (e.g., MDL) with posterior parietal areas permit the cognitive manipulation and the monitoring of the manipulated information in working memory. Interactions between the posterior dorsolateral (PDL) frontal region (in yellow), which includes areas 8 and rostral area 6, with posterior parietal, occipital, and posterior temporal areas permit attentional selection (including conditional rule-based attentional selection) of processed stimuli and contribute to their short-term maintenance through top-down focusing of attention during delay periods. The connections of the posterior dorsolateral frontal region with posterior parietal and temporal areas are not shown so as to not crowd the diagram (see Petrides, 2005). CC, corpus callosum; CG, cingulate gyrus; ec, entorhinal cortex; MTL, medial temporal limbic region.

activations in the frontal region. It should be remembered here that the original debate between Goldman-Rakic and Petrides was not about the general existence or nonexistence of domain-specific dorsal versus ventral activations in the prefrontal cortex. The issue was about two specific prefrontal areas: dorsolateral area 46 (later subdivided into areas 46 and 9/46, see **Figure 1**) and ventrolateral area 45. Goldman-Rakic argued that these two areas could be conceptualized as performing information maintenance functions in working memory, with the fundamental difference being that area 46 maintains spatial information and area 45 maintains nonspatial visual object information (see Wilson et al., 1993;

Goldman-Rakic, 1996). By contrast, Petrides (1994, 1996) argued that area 46 is a critical module for monitoring (tracking of) the contents of working memory, *regardless of whether the material is spatial or nonspatial* and that area 45 is part of the ventrolateral prefrontal region that is involved in the active control of the retrieval of information from memory. Petrides made this argument on the basis of lesion studies to area 46 (which was later divided into areas 46 proper and 9/46) that yielded impairments on both spatial and nonspatial object working memory tasks provided the monitoring of the contents of working memory was taxed. Later, single-neuron recording studies showed that neurons coding location or object information were mixed in the part of the lateral prefrontal region where area 46 lies (Rao et al., 1997).

Often discussions of changes in activity in lateral frontal cortex in functional neuroimaging studies (partly influenced by the debate between Goldman-Rakic and Petrides) are couched in terms of dorsal versus ventral or domain-specific versus domain-nonspecific activations. Would increases of activity in prefrontal cortex be domain-specific or domain-general? Both types of activations should be expected in the prefrontal region during the performance of working memory tasks in functional neuroimaging studies since multiple executive requirements are likely to be recruited depending on the particular requirements of the task, the strategy adopted by the subjects, the control tasks against which activations are assessed, and several other factors (see, Owen, 1997; D'Esposito et al., 1998; Nystrom et al., 2000; Sala et al., 2003; Wager and Smith, 2003). Thus, the fundamental question would appear to be the *specification of the nature of the prefrontal executive process* that is operating in interaction with domain-specific (auditory, visual, tactile, spatial, verbal, etc.) and/or multisensory posterior parietal and temporal cortical areas, rather than a pure classification of prefrontal activations into dorsal (spatial) versus ventral (nonspatial; see Petrides, 1996, 2005, 2013).

In conclusion, there is evidence that the temporary storage of information depends primarily on modality-specific and multisensory temporal and posterior parietal cortical areas. Distinct prefrontal areas in interaction with these posterior storage areas support various aspects of higher-order control processing such as the monitoring of the contents of working memory (the epoptic process), rule-based attentional selection, active-controlled retrieval, inhibitory control, etc. The mid-dorsolateral prefrontal region, which underlies the monitoring of the contents of working memory, in interaction with certain areas of the posterior parietal cortex forms a fronto-parietal circuit for the manipulation of information in working memory.

Abstract

Working Memory refers to a set of cognitive functions that allows humans to keep track of what they are thinking or doing moment to moment. It can also manipulate and process information such as when planning, learning, retrieving stored information, and transforming the information it holds. This article describes the theories that have been developed to explain these human abilities and some of the evidence for these theories from empirical studies of healthy adults and children and of individuals who suffer from cognitive deficits as a result of brain damage.

Definition of WM

Working Memory (WM) can be thought of as the desktop of the human brain, a set of cognitive functions that allows humans to keep track of what they are thinking, what they are doing, or where they are moment to moment. It holds information long enough to facilitate making a decision, learning a new word, mentally imaging the layout of a home, navigating around the world, or remembering what to do next. It can also manipulate and process information such as when planning, learning, retrieving stored information, and transforming the information it holds. This article describes the theories that have been developed to explain these human abilities and some of the experimental evidence for buttressing these theories that have been derived from empirical studies of healthy adults and children and of individuals who suffer from cognitive deficits as a result of brain damage.

Why Is the Concept of WM Useful?

The concept of WM has figured prominently in theories and explanations for human on-line cognition, as well as for offering a basis for understanding how humans accomplish a wide range of everyday tasks. It can be thought of as a mental tool that aids survival; if an organism is to interact successfully with its environment, then clearly there must be some means to record, on a temporary basis, its own most recent actions, keep track of rapid changes in the environment, have some means to plan actions for the immediate future, and to link changes in the environment with stored knowledge gained from past experience. This gives the organism a significant advantage over other organisms that are entirely driven by automatic responses to external stimuli that signal basic needs. Examples of how this mental tool is used in everyday interaction with the environment highlight its utility. Humans use WM every time they have to solve a problem, to perform a mental calculation, to recall where an object has just been laid down, to navigate around an unfamiliar environment, or to repeat an unfamiliar foreign word that has just been heard.

From these examples, it is clear that the concept is much broader than the more traditional idea of short-term memory. The concept of WM arose from the need to provide a theoretical account of a wide range of everyday tasks that require both temporary memory and on-line cognition. It is also much broader than what some people might think of as conscious experience. Our conscious experience is the result of how our brain interprets the information in our environment and stored information about past experiences. So, not everything that is available to conscious inspection necessarily reflects the actual functioning of on-line cognition, and not all functional aspects of on-line human cognition are available to conscious inspection (Pylyshyn, 1973). WM includes aspects of on-line cognition that are not necessarily available to conscious inspection as well as some elements that might be.

Until the early 1970s the focus of research on temporary memory and on-line cognition involved experimental studies of memory for random sequences of words, letters or digits, with the everyday example of recalling telephone numbers while dialing. However, a mental faculty would not have evolved to deal with these relatively artificial tasks, and therefore the concept of WM is intended to encapsulate on-line cognition and temporary verbal and visuospatial memory in both laboratory tasks and in everyday life.

Theoretical Views of WM

Most memory researchers consider WM to be a useful concept that uses relatively few assumptions to explain a wide range of experimental evidence as well as important aspects of everyday cognition; it is a system with limited capacity, which loses information over periods of seconds, whose contents are subject to displacement by new input, and which interacts and is supported by other parts of the cognitive system such as stored knowledge or the products of perception. Most theories of WM include these features; however, there remains a debate as to its precise characteristics. Some theories view memory as a largely unitary system with WM as the sum total of what is currently activated from the store of knowledge, skills, expertise, and past events. Others view WM as separate from the long-term store of knowledge and events accumulated over the lifetime. However, even among the theories that view WM as separate from the long-term store, there is some amount of discussion as to whether the cognitive functions of WM are supported by a single flexible system that provides both temporary storage and on-line processing, or that comprises multiple components, each specialized for a particular function, but that work

together to support task performance. There are multiple books as well as thousands of published research reports on different aspects of WM. As at the time of writing, books by Baddeley (2007) and Osaka et al. (2007) offer the broadest coverage, with more recent shorter reviews in Baddeley (2012) and Logie (2011).

The first type of theory, that memory is a unitary system and that WM is simply the currently activated knowledge, can account for a wide range of data from experimental psychology with healthy adults, including the ability to bring rapidly to mind information related to areas of personal expertise. Theories of this kind can very successfully explain how chess masters can play several games simultaneously, expert waiters can recall details of meal orders from large groups, and why burglars can recall better than householders, or indeed the police, details of houses related to their crime. Expertise extends the apparent capacity of WM, but there is some recognition among proponents of this type of theory of the need for a temporary memory system to deal with completely novel or unfamiliar material. There is also a need to have some kind of memory system that can be updated moment to moment: For example, in order to understand what you are reading now, you have to remember what you read immediately before, and to continually update your memory for what you have just read as you progress through the text. Something similar is needed to keep track of a conversation, or of cars nearby when driving on a busy motorway. In the distant past when humans did not have supermarkets and had to hunt for their food or to escape a predator, there would have been a need to continually update memory for where the animal is as it moves through the trees and bushes if there is any chance of catching something to eat or to avoid being eaten. The same would still be true for many animals and also some humans today. In fact, anything that we do throughout our waking hours that involves moment to moment changes in our environment requires a WM that can keep track of those changes, and humans would not have survived very long if they did not have some form of WM.

The view that WM is no more than the sum total of currently activated experience and memories for past events also runs into difficulty when considering dissociations that are apparent from studies of healthy adults performing more than one task at the same time. There is substantial evidence that healthy adults can perform two quite demanding tasks concurrently such as walking and talking. In research under more controlled conditions this can be studied by, for example, hearing and recalling a random sequence of numbers, such as 3-7-4-6-7-9, and, at the same time using a stylus to follow a randomly moving target on a computer screen. There is very little impact on the ability to recall the number sequence correctly or to track the moving target when they are performed together compared with when each task is performed on its own, and this can be accomplished without any particular expertise or training. Complementary studies have shown that placing a heavy demand on temporary memory places few, if any restrictions on retrieval of stored knowledge about past events or that is linked to expertise. These findings suggest that the human cognitive system may comprise several components, each specialized for particular kinds of tasks, which may operate in parallel even if our conscious experience is of only one component operating at a time. The findings also point to the idea that WM is best considered as being separate from, but interacting with, the system that stores previously acquired knowledge of the world and of past experiences.

The unitary view of memory also has difficulty explaining patterns of impairment and sparing in individuals who suffer from cognitive deficits as a result of brain damage. The cognitive impairments are often selective, for example, with very poor performance on immediate memory tasks (such as repeating back a random sequence of digits) coupled with normal performance on long-term retention (such as recalling events that occurred weeks, months, or years previously). The converse dissociation also occurs, namely normal memory for something that happened within the last few seconds contrasting with very poor retrieval of details about events that happened a few hours, days, or months previously, or difficulties in learning something new. Theories assuming that WM comprises temporary activation of relevant information from long-term memory would predict that if long-term memory access is impaired then temporary activation of long-term memory should also be impaired. Theories that assume WM to be a functionally separate part of the cognitive system can account more readily for the different patterns of cognitive impairment observed following brain damage, as well as for the data patterns from healthy adults, and therefore may be more useful.

The Case for Multiple Memory Systems

During the first half of the twentieth century, the prevailing view in North America was of human memory as primarily the result of observable learning of associations, and theories of learning dominated. During the same period in Europe, memory as a cognitive concept was more prevalent, for example in the work of Bartlett, Broadbent and Zangwill. By the mid-1950s, the latter started to become the more generally agreed view, and the spread of a cognitive approach to memory on both sides of the Atlantic gave rise to major new avenues of research. Very quickly it became clear that memory was best thought of as comprising at least two elements, with one focusing on temporary or short-term retention and the other on long-term retention. This reflected a dichotomy proposed originally in the seventeenth century by the British philosopher John Locke who suggested that the 'faculty of retention' comprised 'contemplation' or 'keeping an idea in mind,' and that this was separate from 'memory' or the 'storehouse of ideas.' This distinction appeared again in the late nineteenth century when the North American philosopher and psychologist William James referred to primary memory as holding information in mind which he contrasted with retention as storing records of life experiences and acquired knowledge.

During the 1960s, the contrast between primary memory and what then became known as secondary memory was demonstrated experimentally. For example, when healthy adult volunteers are asked to retain sequences of words for immediate recall in any order, omissions tend to occur among words from the middle part of the list and much better recall is observed for items close to the beginning or close to the end of each list. If instead, the volunteers are asked to recall the items following a delay, performance on the last few items is no better than it is for items in the middle of the list. However,

initial items in the list retain their advantage despite the delay. These contrasting patterns were thought to support the idea that two memory systems are reflected in recall of different parts of the list: the early list items are thought to be rehearsed and transferred into a longer term memory system, or secondary memory. As the list progresses, rehearsal becomes more difficult and therefore few items are transferred to a long-term store. The items in the final segment of the list are presumably held in a temporary memory system, or primary memory, whose contents are lost unless recall is immediate. The advantage for the items in the early segment of the list is known as the 'primacy effect,' and the advantage for the final items with immediate recall is known as the 'recency effect.'

Further support for the dichotomy comes from people who, following brain damage, suffer from specific types of memory impairment. One type of such patients is characterized by an inability to learn new material, a condition referred to as anterograde amnesia. The damage usually involves an area of the brain known as the hippocampus. When such people are tested for immediate free recall of word lists, their pattern of recall lacks the advantage for the initial items in the list (i.e., no primacy effect) but they show a normal recency effect. This suggests damage to the memory system responsible for retention of the early items but normal functioning of the memory system responsible for the recency effect. These people can also keep track of normal conversations over a few minutes, but just an hour later will have forgotten that the conversation took place. So, people with anterograde amnesia seem to have a primary memory that functions normally, but a longer-term memory that is malfunctioning. Another type of memory impairment shows the opposite effect in which there is great difficulty remembering and repeating back sequences of letters, numbers and words, but completely intact use of longer-term memory. The fact that ability to remember verbal material over short periods of time can be impaired independently from the ability to undertake new learning, suggests that these reflect two different kinds of memory systems in the brain. That is, primary memory is not simply activated long-term memory.

Developing the Concept of WM

The idea of primary and secondary memory provided a useful framework to account for the accumulating body of experimental data in support of a two-component memory system. However the traditional study of primary memory was limited by the fact that virtually all of the research relied on experiments with presentation and recall of words, letters, or digits. It is clear that we can also retain information about the appearance of objects and scenes, shapes, colors, and sequences of movements, as well as names and verbal descriptions. Therefore, from the late 1960s, primary memory began to be seen as a system that could support temporary retention of different kinds of material as well as offering a means to process and manipulate that material. The dominant or 'modal' concept then began to be identified as a shortterm, or WM processing and storage system. This 'modal model' retained the notion that information was transferred from the senses, via WM to secondary, or long-term memory. In this sense, WM was seen as a form of gateway, or temporary waiting space between input from the outside world and stored knowledge. It also incorporated the assumption that WM has a maximum capacity that could be used by storage, by processing, or by elements of both.

However a number of features of this model came under pressure from the 1970s onwards. The recency effect, once thought to be a major source of support for a temporary memory system, also was demonstrated in longer-term recall. For example when recalling visits to movies, one can recall where the car was parked, or attending rugby matches, individuals often can recall details of very recent events, even if these had occurred several days or weeks before, but have rather poorer recollection of similar experiences that happened previously. This demonstrated that recency was not unique to a temporary memory system. From this came the suggestion that memory loss functioned a little like observing telephone poles as they recede into the distance. Memory for the last visit to a restaurant a few days previously can be vivid and detailed, just as the closest telephone pole can be seen very clearly. Memory for the second last, or third last or fourth last restaurant visited becomes progressively less clear with increasing numbers of restaurant visits, just as it becomes more difficult to distinguish between different poles the more intervening poles are in view. This suggested that forgetting came from memories interfering with one another, and that recent events are remembered well because there are fewer other memories to cause interference. This would then apply to memory for events that happened a few seconds ago as well as memories for events that happened a few days or weeks previously. Also, there were demonstrations that semantic knowledge could be used to help support short-term retention. For example immediate free recall of real words is better than recall of nonsense words, suggesting that the stored knowledge about the real words (such as their meaning) can support primary memory, and so primary memory might simply comprise activated secondary memory.

There was, and still is, some debate as to whether research findings such as those just described might undermine the view that primary memory is separate from secondary memory. However, the separate memory systems view is still needed to explain the different kinds of memory problems found in people with contrasting forms of brain damage. So, patients with a dense amnesia typically show a normal short-term recency effect, but do not show long-term recency effects. One resolution to this debate is that better memory for recent events might be a property of any human memory system (short or longterm). So, showing recency effects over short and long periods does not mean that these effects reflect the operation of the same memory system. The evidence for short-term semantic coding showed that the memory systems interact, with any one memory task probably drawing on several different aspects of the cognitive system depending on task demands, rather than reflecting a single memory system.

Although the modal model survived the discovery of long-term recency and semantic information in immediate memory tasks, another core assumption of the model was challenged by the discovery that information from vision or hearing could reach long-term memory without being available in WM. Evidence for use of semantic codes in tasks thought to require WM suggested that information from the senses might first activate stored knowledge related to the sensory input before it reaches WM. So, this suggests that the flow of information is

the other way round from that suggested by the modal model, and activation of stored knowledge following sensory input acts as the route in to WM. Again, the insight came from studies of brain-damaged individuals: one famous case is that of patient 'PV' who, following a stroke in the sylvian region of the left hemisphere, presented with a very severe deficit in retaining sequences of words or digits for immediate recall, but had no difficulty in retrieving details of autobiographical events and proved well able to learn from new experiences. The pattern for PV and other similar patients reported subsequently suggests that access to long-term memory does not depend on normal function in short-term verbal retention, either for new learning or for recall of past events (reviews are given in Vallar and Shallice, 1990).

Additional evidence about the characteristics of WM comes from patients who suffer from a disorder known as unilateral spatial neglect. This arises most commonly from damage to the right parietal cortex of the brain, and such patients typically are unable to report details of scenes or objects to their left, despite having normal vision. A few patients show unilateral neglect only for information in their mental image or immediate memory for scenes. For example, one patient 'NL' (Beschin et al., 1997) could quite readily report details of everything in his immediate environment. However, if he was asked to close his eyes, he could only report from memory details that were on his right. Moreover, if asked to recall details of a familiar scene such as the town square in his home town he could recall only those details that were on his imagined right. This was not a problem of accessing his long-term memory, because when asked to imagine himself standing at the opposite end of the square, he could then report details that were now on his imagined right but had been omitted before from a different imagined viewpoint. This pattern demonstrates a clear dissociation between the processes of perception, which for NL were perfectly normal, the contents of his long-term memory, which again was normal, and the operation of his visual WM, which was dramatically impaired. This further suggests that WM does not act as a gateway between perception and long-term memory as assumed by the modal model, but instead deals with information that has been activated from long-term memory.

Studies of healthy adults have also demonstrated that the contents of WM are interpreted, for example in studies of memory for ambiguous figures. Figure 1 can be interpreted in one of two ways, either as a duck or as a rabbit, and if we continue to inspect the figure then our interpretation 'flips' between one and the other. However in some ingenious experiments, Chambers and Reisberg (1985 – see Cornoldi et al., 1996) showed this figure for only a brief time to a large number of volunteers who were asked to report from their memory what the figure depicted. All of the volunteers reported it as either a duck or a rabbit, but none of them could then reinterpret their image in memory and see the figure as anything other than their first interpretation. Nevertheless, they could do so when asked to draw their image on paper moments later. So, looking at the ambiguous figure allows a switch between seeing it as a rabbit or as a duck, but the representation of the figure in WM is linked closely with the initial interpretation of what we saw. In other words, the contents of WM are interpreted before they enter WM. This offers quite convincing evidence that perception feeds into long-term memory, which activates relevant knowledge for manipulation with WM (for discussions see Cornoldi et al., 1996; Logie, 1995, 2011).

Figure 1 Example of the duck-rabbit ambiguous figure.

A second assumption of the modal model was that of WM as a single, flexible, limited capacity system that could undertake both temporary storage and some processing of the material being stored. This theme remains in one contemporary, and influential strand of WM research that has focused on measures of individual differences in cognitive capacity. In a typical task, healthy adult volunteers are asked to read a series of sentences. The requirement is to recall the last word of each sentence after all the sentences have been presented. The number of sentences is gradually increased until the participant can no longer accurately recall all of the final words, and the maximum number of words that can be recalled is taken as a measure of the individual processing and storage capacity. The measure, in various forms, has been shown to correlate well with other measures of cognitive ability such as reading comprehension or mental arithmetic performance, and with general intelligence (e.g., Kane and Engle, 2002). These correlations are then used to argue that WM is a mental capacity for processing and storage that can be applied to a wide range of both laboratory and everyday cognitive tasks. In this sense, the sentence 'span' (or WM capacity) measure has been quite useful, and offers the basis for a standardized test of cognitive ability. Some researchers have even suggested that it might replace standard IQ tests.

Although the above approach has significant value as a measure of individual differences in mental capacity, the underlying theoretical assumptions are that there is a single flexible cognitive system supporting the memory performance as well as the processing of material, such as reading the intervening sentences. One possible alternative view is that the WM capacity task actually relies on several different aspects of cognition, and that this same range of cognitive functions is employed for other complex cognitive tasks such as reading comprehension. A further limitation is that the test provides only a measure of memory in the context of processing (retention of the final words while reading). Typically, there is no measure taken of performance on the processing component of the task. In a small number of tests of the assumption that the same system supports memory and ongoing processing, a separate measure has been taken of processing capacity by asking volunteers to verify each of the sentences for their semantic content without a memory requirement. Memory ability was then measured independently by asking volunteers to recall lists of individual words without any requirement to verify sentences. Participants were then asked to combine verification of each sentence with recall of all of the final words for the sentences, and the task demands were set at the maximum that had been determined for each task component separately. If WM were a single flexible, limited capacity system,

we might expect performance to be very poor when these two demanding task elements were combined. Results have shown that despite the high processing demand and high memory demand, performance levels on both elements of the task remain very close to those obtained when the memory task and the processing task are performed independently. Moreover, there are typically poor correlations between the processing task scores and the memory task scores, and a combined score that includes both processing and memory scores shows much higher correlations with other measures of mental ability than does the score for recall of the final sentence words alone.

These results point to the notion that temporary memory might be served by different aspects of the cognitive system from those used to support on-line processing. This argument in turn suggests that WM might be best thought of as the orchestrated operation of multiple cognitive instruments, each one with a specific role for temporary memory or for processing. For any given task, there is a selection of which instruments are needed. Some of these instruments might be needed to perform at the limits of their capacity. Other instruments might be needed to perform the task, but they make a contribution that is well within the limits of their capacity. So, looking at the differences between people in the maximum score that they can obtain on a complex cognitive task will reveal something about the overall mental ability of each individual, but will not reveal much about the cognitive instruments or components that are available, or how those components work together to maximize task performance. For more detailed discussion of this point see Logie (2011).

WM as a Multiple Component Workspace

The most influential model of a multicomponent WM was originally proposed in 1974 by two British scientists, Alan Baddeley and Graham Hitch. The model included some elements of the modal model by incorporating processing and memory, however these were viewed as distinct. Three components were originally proposed to provide respectively temporary verbal storage, temporary visuospatial storage and a coordinating or 'executive' function. The verbal storage component was originally named the articulatory loop, although subsequently it has been referred to as the phonological loop, and to consist of two components, a passive phonologically based temporary store and a mental verbal rehearsal process. The visuospatial component was originally referred to as the visuospatial scratch pad, but has subsequently been thought to comprise a specialist temporary memory store (or visual 'cache') for retaining the visual appearance of objects and scenes linked to a system (an 'inner scribe') for retaining, and possibly rehearsing, sequences of movements and more dynamic properties of scenes. The coordinating mechanism was referred to as the central executive, but in more recent years has been thought of as a collection of different executive functions that collectively can support switching between tasks, updating the contents of WM, inhibiting irrelevant information, the coordination of multiple task performance, the allocation of attention and the implementation of strategies and heuristics used in problem solving, and learning and retrieval.

A schematic representation of a recent version of the multiple component model is shown in Figure 2. The diagram illustrates the various specialist subcomponents in addition to the suggested flow of information from perception through a long-term knowledge base into WM. In the latter sense the contents of WM comprise some of the products of perception and of subsequent mental processing. WM can then be considered as a multicomponent workspace that stores and manipulates information, which has been activated from the long-term store, rather than as a primary route into long-term memory from the environment. Detailed discussion of the evidence for the features of the model can be found in Logie and van der Meulen (2009), Logie (2011), and Baddeley (2012).

This conception of WM fits neatly with the notion that people are strategic in how they use their cognitive functions. For example, in recalling a list of words, this can be accomplished by rehearsing the sounds of the words, thinking about their meaning, organizing them into groups, remembering what the words look like when printed, or imagining the objects or concepts to which the words refer. As a result, a phenomenon such as the phonological similarity effect (see above) with visually presented words only appears if the participants rely on mentally rehearsing the sounds of words

Figure 2 Schematic diagram of a recent version of the multiple component model of working memory.

prior to recall. Observing the phonological similarity effect can then indicate how the people are remembering the words. However, there is evidence that some participants in these experiments spontaneously use other strategies that might rely on visual or semantic codes, and for them the phonological similarity effect does not appear (e.g., Logie et al., 1996). The same argument holds for other well-established phenomena such as the recency effect. Different people might perform the same task in different ways. Moreover, as people get older, some aspects of WM remain relatively intact (primarily verbal memory ability), whereas other aspects of WM start declining in early adulthood and continue to decline throughout life (primarily visual memory ability). It also appears that older people might perform WM tasks in different ways than do younger people (see Johnson et al., 2010). The differential changes across age, and differential strategic use of different aspects of WM would not arise if the material did not activate knowledge stored in long-term memory prior to it being held in WM for the period until recall is required. Nor, would it arise if there is only a single, general purpose WM system. The evidence is easier to explain if we assume that WM comprises a range of specialist cognitive functions that can act together when performing a cognitive task.

Applying the Concept of WM

The idea of a multiple component WM has proved useful in understanding some of the cognitive deficits suffered by individuals with brain damage as well as accounting for important aspects of healthy cognition. Discussed above are some of the insights into cognitive deficits arising from the use of the model, and how studies of people with such deficits help the understanding of normal cognition. There have been several other areas of application, including the use of the phonological loop in explaining important aspects of vocabulary learning and of mental arithmetic. For example, one feature of the phonological loop is that it can retain a recently heard word, mentally rehearse the word, and then generate the word as articulate speech. A number of studies have examined the ability of young children to repeat aloud new or nonsense words that they have just heard. Their ability to do so correlates well with their general competence in language and predicts their language ability several years later. Patients with severe verbal short-term memory deficits also appear to have difficulty acquiring new foreign vocabulary. These findings have led to the suggestion that the phonological loop is a cognitive function that has evolved to support the acquisition of language, and that has the emergent property that it can support temporary verbal memory.

Among the acquired skills that appear to depend on the phonological loop are counting and mental arithmetic. Keeping track of a running total in counting, relies on subvocal rehearsal of the counting sequence, while keeping track of partial solutions in mental arithmetic again appears to rely on subvocalization of the subtotals involved, unless the solution is already well learned. For example, for most people the answer to $4 + 5 = ?$ would be available without the need for mental calculation, because it would be recalled as an arithmetic fact. However the answer to $23 + 19 + 48 + 34 = ?$ would require a series of operations with temporary memory for the subtotals (held in the phonological loop) as each part of the sum is completed. Evidence for these conclusions arises from studies in which volunteers perform counting or mental arithmetic while suppressing articulation through repeating an irrelevant word. Accuracy in counting and in arithmetic is disrupted by this procedure but is not disrupted by performing other irrelevant tasks such as tapping the table in a regular pattern or even when being presented with irrelevant speech sounds. The phonological loop therefore seems to support accuracy in counting and arithmetic.

The visuospatial resources of WM can support a wide range of other everyday cognitive tasks such as remembering where we are on the page while reading, maintaining and updating a representation of objects in our immediate environment, mental scanning to plan a route around a familiar town, or imagining the configuration of furniture in an empty room. The visual cache appears to be able to support memory for the visual appearance of letters and words, and to support temporary memory for combinations of colors and shapes, as well as visual patterns. We are not necessarily aware of the contents of this visual temporary memory, but we can retrieve information from it when it is needed. The visual cache does not seem to be directly linked with visual perception, and can store visual information that has been activated from hearing the name of an object. So, for example, hearing the words 'red circle,' 'blue cross,' 'green triangle,' would activate stored visual knowledge about those words, allowing a temporary visual memory to be created comprising those particular shape–color combinations. A temporary visual memory could likewise be created by seeing a red circle, a blue cross and a green triangle. The temporary visual memory system (the visual cache) that holds the information appears to be the same, regardless of whether the information was heard or seen. A second temporary representation could also be created based on the sounds of the words, and this could be held in the phonological loop as a sequence of word pairs. Again, it would not matter if the word sounds had been heard, or had been activated from stored knowledge when looking at the colored shapes. A third temporary memory for the same material could involve the creation of a meaningful integrated mental image that includes all three colored shapes in a recognizable object, for example in the form of a colorful ice cream cone. This would more directly involve activation of stored knowledge and additional cognitive functions that allow manipulation of the information to support creative thinking. When asking someone to remember which colored shapes they saw or heard, their memory could come from any or all of these three types of temporary memory representation. So, WM then can function as a set of different cognitive functions acting together when confronted by tasks in experiments and in our daily lives.

Conclusion

WM is an evolving concept, which may be subject to change in the light of new evidence or questions as to its detailed characteristics. It is broader than the concept of short-term memory in that it not only includes short-term retention of information, but also includes the selection, processing and manipulation of

that information. It encompasses separate short-term memory systems for retaining different kinds of information such as the sounds of words, the appearance of shapes or colors or their combination, and sequences of actions and movements. Crucially it allows understanding of a great deal of evidence and phenomena from laboratory tasks performed by healthy individuals, from studies of individuals with specific forms of brain damage, and from everyday experience.

Abstract

Autonomy, the condition or quality of being self-governing or free from excessive external control, has been a vital concept in theory and research on human growth, development, well-being, and motivation. To demonstrate the widespread significance afforded the concept of workplace autonomy (and the crucial practical consequences associated with it), in this article, we review the historical foundations, significant models, and emerging streams of research in this area of study. This article leads us to conclude that both individual and collectivist autonomy are highly beneficial for individuals, organizations, communities, and societies.

For decades, autonomy has been a vital concept in theory and research on human growth, development, well-being, and motivation. Autonomy can be defined as the condition or quality of being self-governing or free from excessive external control. According to Immanuel Kant, the eighteenth century German philosopher often credited with laying the groundwork for modern philosophy, autonomy is important to human beings because it is the foundation of human dignity and the source of all morality (Hill, 1991). The dignity (poise and self-respect) of an adult is usually based on possessing some meaningful degree of control in making the decisions that deeply affect his or her life. Likewise, the source of a person's morality lies in the volitional self that rises above socially conditioned desires and partisan attachments in order to adopt impartial ethical principles and standards of conduct.

More recently, scholarly interest in the concept of autonomy has led to extensive research on workplace autonomy, the domain of life often seen as most essential to human accomplishment, enrichment, and fulfillment. To demonstrate the widespread significance afforded the concept of workplace autonomy (and the crucial practical consequences associated with it), in this article, we review the historical foundations, significant models, and emerging streams of research in this area of study.

Autonomy and the Individual

During the 1960s, amid massive social upheaval in many of the advanced industrial nations of the world, organizational and management theorists began to turn their attention to the sources of discontent in the workplace, manifesting in "accelerating absenteeism, job turnover, shoddy workmanship, sabotage, and the greatest outbreak of wildcat strikes since the 1930s" (Greenberg, 1975: p. 192). Several now classic texts called attention to the neo-Marxist thesis of alienation and the notion that lack of control over the product and process of work would lead to intense and widespread feelings of powerlessness, meaninglessness, social isolation, and self-estrangement (e.g., Blauner, 1964).

In one of the first systematic attempts to address the phenomenon of work alienation and freedom, Hackman and Oldham (1976) developed the Job Characteristics Model, a framework that focused attention on autonomy and four other key factors involved in designing enriched work. Work designed to be complex and challenging (characterized by high levels of autonomy, skill variety, identity, significance, and feedback) was theorized to promote high intrinsic motivation, job satisfaction, and overall work performance. Of these characteristics, autonomy is arguably the most studied. Decades of research on this widely cited model have shown that job scope or complexity, an additive combination of autonomy and the four other job characteristics, (1) is correlated significantly with more objective ratings of job characteristics, (2) may be reduced to a primary factor consisting of autonomy and skill variety, and (3) has substantial effects on affective and behavioral reactions to work, mostly indirectly through critical psychological states such as experienced responsibility for the outcomes of the work. There is some evidence suggesting that the positive effects of complex and challenging work have thresholds, but the main lesson we can draw up from this line of research is that the experience of autonomy at work has positive consequences ranging from higher job performance to enhanced general well-being. Studies continue to support the model across nation-states, industries, jobs, and teams (see DeVaro et al., 2007).

Another influential model and line of ongoing research in which autonomy at work is central was launched by Karasek's (1979) study of national survey data from Sweden and the USA. In this research, he proposed the Job Demands–Job Control Model that included a thesis about the causes of physical and mental strain and health problems. Job demands include requirements for working fast and hard, having too much to do and too little time to do it, conflicts among demands, and personal conflicts with one's role. Job control is specified in terms of decision latitude and relates to the theme mentioned earlier about possessing some meaningful degree of control over decisions that deeply affect one's life. Karasek (1979) proposed two dimensions to job control (authority to make decisions on how to work and having say over what happens; and latitude to use a variety of skills on the job). These dimensions parallel Hackman and Oldham's (1976) two central concepts of autonomy and skill variety. The main proposition in Karasek's original model was that when jobs are

simultaneously high in demands and low in decision latitude, physical and mental health problems are more likely to occur – the 'high strain job' (Karasek, 1979: p. 288). Demanding jobs that permit autonomy through high decision latitude are challenging and create opportunities for arousal, learning, and healthful response, thus mitigating the stressful effects of demands and generating the potential for job satisfaction and life fulfillment.

As with the Job Characteristics Model, research on Karasek's (1979) framework has underscored the importance of autonomy at work while also revealing some of the intricacies involved in explaining the specific processes through which autonomy exerts its positive effects. Research on Karasek's original Job Demands–Job Control Model has been mixed. Many studies reported that demands have negative effects regardless of the degree of job control, but in other studies, the predicted interaction effect has been found. In response, researchers began to develop the model further by examining the role of individual differences moderating the importance of decision latitude. For example, the role of self-efficacy and the role of proactive personality have been explored. It was found that high strain was mitigated when decision latitude was exercised by more self-confident and proactive individuals.

Karasek and others have developed an enhanced model that includes job demands, control, and support. Recognizing the long history of research demonstrating the importance of social support and its effect on well-being and productivity (e.g., from coworkers and supervisors), the enhanced model included social support as a third dimension (Karasek and Theorell, 1990). In a recent meta-analysis involving 106 studies, Luchman and Gonzalez-Morales (2013: p. 45) found that all three dimensions (demand, control, and social support) contributed (each in their own way) to the experience of work, thereby supporting the model and its dimensions. Their findings support the conclusion that the highest levels of well-being in work environments are characterized by high control (autonomy), low demands, and supportive supervisors and coworkers. Research on the model of job control, demands and support underscores the importance of autonomy and other characteristics of jobs as essential to understanding the quality of work experiences.

A prominent approach to theorizing perceptions of autonomy, the internal–external locus of control model of human personality, proposed that individuals perceive that their actions can affect the events in their lives, but vary in the degree to which they believe forces outside their control typically influence the events (Langer, 1977). Some people (externals) have a relatively consistent tendency to perceive that the outcomes in their lives are governed by external forces, such as powerful others and social conditions, fate, luck, or chance. Others (internals) have a relatively consistent tendency to believe they control their own destiny; they perceive themselves as masters of their own fate and as in control of the actions and events that affect their lives. This model has been researched extensively, leading to conclusions that people who do not see themselves as self-governing (externals) are handicapped in numerous ways (e.g., less effective performance after controlling for cognitive ability and conscientiousness – Hattrup et al., 2005; greater psychological strain from workplace conflict, Dijkstra et al., 2011). Recent research, however, suggests that a more nuanced cultural approach to understanding locus of control may be warranted. In a meta-analysis integrating 40 years of locus of control research, Cheng et al. (2013) found evidence that suggests that external locus of control does not have the same negative connotations in collectivist societies that it does in individualist societies. They propose that in collectivist cultures such as Mainland China, "a sense of control may not be confined to control originated from oneself but may also encompass control derived from one's social network members" (p. 176).

Among the models of human growth and development that are centered on autonomy, the most theoretically sophisticated approach has been developed around the basic psychological needs of autonomy, competence and relatedness, and the concepts of self-regulation and intrinsic motivation (Ryan and Deci, 2000; Niemiec et al., 2010). Self-determination theory (SDT) proposes "higher behavioral effectiveness, greater volitional persistence, enhanced subjective well-being, and better assimilation of the individual within his or her social group" result when individuals act from motivations that emanate from the inner self (intrinsic motivation) rather than from sources of external regulation (Ryan and Deci, 2000: pp. 72–73). Although not without controversy (due to the entrenched belief that tangible rewards primarily govern behavior), research in a wide array of social conditions has demonstrated that individuals develop a perceived external locus of causation (i.e., a sense of diminished autonomy) when tangible rewards are administered contingently, based on evaluated performance at a task. For self-determination theorists, it is the experience of an external locus of causation (or the belief that one's actions are controlled by external forces) that undermines the most powerful source of natural motivation and that (when chronic) also can lead to stultification, weak self esteem, anxiety and depression, and alienation. Thus, health and well-being as well as effective performance in social settings are closely related to the experience of autonomy. Interestingly, Ryan and Deci (2000: p. 74) point out "autonomy refers not to being independent, detached, or selfish, but rather to the feeling of volition that can accompany any act, whether dependent or independent, collectivist or individualist."

A related framework for understanding workplace autonomy may be found in the widely circulated literature dealing with psychological empowerment. This framework builds on job characteristics research, SDT, and models of participation in decision-making and power equalization in the workplace. It specifies cognitions of perceived control and experienced psychological states that are inherent to; autonomous work. In a foundational article, Spreitzer (1995) defined psychological empowerment as a process manifesting in four primary cognitive states: (1) meaning, (2) competence, (3) self-determination, and (4) impact. In combination, these key cognitive states lead to high intrinsic motivation, work engagement, creativity and innovative behavior, organizational citizenship behavior, and quality work performance as well as personal benefits for employees such as reduced psychological strain (Seibert et al., 2011). Psychological empowerment research runs parallel with concepts of empowering leadership (e.g., Zhang and Bartol, 2010) and these concepts may be traced back to research conducted decades earlier that focused

on the beneficial effects of democratic, participative, and even laissez-faire leadership. What is especially noteworthy about research on psychological empowerment is that it is a highly integrative approach to theorizing, drawing together elements of workplace autonomy that have been conclusively linked to important organizational and personal outcomes.

Autonomy and Groups and Teams

The theme of workplace autonomy also runs through over six decades of research on groups and teams in organizations. Of primary concern here are the streams referred to by Moldaschl and Weber (1998) as the sociotechnical systems theory approach (STS) and the lean management approach. Both approaches focus on teams that are, to varying degrees, autonomous or self-organizing. Self-organizing teams have been theorized as having processes of self-management and collaborative teamwork. In self-organizing teams, members experience relatively high autonomy by collectively controlling, for example, the pace of work, task allocation, performance evaluation, recruitment and selection of new members, training, and even reward distributions. As noted by several researchers, because groups can undertake much larger pieces of work than individuals can, the potential to experience positive outcomes through heightened control is greatly enhanced.

Beginning with Trist and Bamforth's (1951) classic study of autonomy among long wall coal miners, through to recent reviews and meta-analyses of research in the STS tradition, positive results have been reported. Despite 'substantial variance' in research findings regarding the consequences of autonomous work groups (Guzzo and Dickson, 1996: p. 326), positive impacts on motivation and productivity (especially performance quality and cost savings), attitudes and perceived quality of work life, and (to a lesser extent) attendance and retention are routinely reported. Failures of some STS projects and the fact that STS interventions in organizations have not been used as widely as initially anticipated have been attributed to poorly designed (imbalanced) programs and internal political conflicts.

The lean management approach, used initially by Japanese manufacturers such as Toyota, differs from the STS approach primarily in the degree of autonomy experienced by team members. The lean management approach tends to be more supervisor-centered as team leaders are appointed rather than elected, decision-making is consultative rather than consensual, and the domain of decision-making authority for the team is more limited. Ilgen et al. (1993) noted that when team-based structures are created in organizations, there is a tendency to retain an overarching hierarchical structure and to require teams to report to leader-managers in a very formal and traditional way. In situations where teams are teams mostly in name, autonomy is very limited, leading to negative results. When interventions empower teams to become more self-directed and autonomous, results tend to be positive across a number of indicators, including financial performance (cf Latham and Pinder, 2005).

While the body of research on teams is rapidly mounting, with much of it supporting the benefits of autonomous or semiautonomous teams, scholars continue to call for a better understanding of the causal mechanisms that produce beneficial results and for complex models examining micro and macro contingencies (Delarue et al., 2008). They continue to explore new areas of research, such as the relationship of individual autonomy to team autonomy, responses to conflict in teams, team dynamics in service delivery firms, intergroup coordination across autonomous work teams, and shared leadership in teams.

Many scholars are quick to point out that work is often done by groups that are merely labeled 'teams' by managers but that lack the defining qualities of teams (see Procter and Burridge, 2008). Others point out that teams are not a panacea for producing high organizational performance or team members' well-being (e.g., D'Innocenzo et al., in press). Moreover, despite the positive results often attributed to autonomous and self-organizing teams, one cannot assume that the approach frees members from hierarchical control that automatically creates emancipated practice. Some writers contend that while workers in the typical self-managed team situation might feel a measure of influence, upon closer inspection, it is only an illusion of self-control. This theme is developed further by Ezzamel and Willmott (1998) and others who show that teams, through peer pressure and behavioral regulation, can intensify work and coerce their members in ways that are perhaps even more tyrannical than are the forms of control exercised by managers.

Autonomy and Organizational Democracy

The final stream of research on workplace autonomy that we will consider is best labeled organizational democracy or workplace democracy and is more familiar to researchers in Europe than in North America (see the academic journal *Economic and Industrial Democracy* (1980) – current volumes, for a review of this approach). The case for large-scale, organizational democratization is frequently linked to arguments asserting various benefits of autonomy realized through power equalization and participation in decision-making. Participatory structures are advanced as an antecedent to human psychological and social development (through, for example, opportunities for self-expression, creativity, achievement, or voice in how one's work is done) and as a formula for increasing organizational efficiency, productivity, and competitiveness.

Organizational democracy continues to be a popular theme, especially in the international management literature. Contemporary debates raise a range of provocative questions about the most fundamental issues. For example, Kokkinidis (2012) raised serious questions about whether, in contrast to direct workplace democracies, representative forms only serve to legitimize hierarchical structures. Harnecker (2009) also pushed on the limits of existing workplace democracies by asserting that workplace democracies such as cooperatives are not sufficient for meeting the social needs of communities if they are not embedded in the democratic planning processes of their surrounding communities.

The tradition of organizational democracy is important as a beacon for genuine social and economic reform because it helps sharpen distinctions among the varieties of macro-factors operating in the world that shape self-regulating organizational

systems and their effectiveness. Consistent with this approach is the conclusion that self-directed, autonomous teams tend to be more effective in nations other than the USA. Dobbin and Boychuck (1999), for example, found that national employment systems shaped the degree to which autonomy was realized (relatively high in Nordic countries and relatively low in the USA, Canada, and Australia). Why should this be so? Studies of workplace autonomy from the standpoint of organizational democracy provide some answers to this question and open the field up in at least two important ways. First, they suggest how, for example, individualistic and collectivist nation-state cultures shape attitudes and other reactions toward team-based, democratic organizing, in effect constraining and prefiguring the effectiveness of any intervention aimed at enhancing workplace autonomy. This point also corresponds with Guzzo and Dickson's (1996) statement that the effects of team-based organizing are highly situationally dependent and extends it into the realm of nation-state contingencies. Second, they suggest a need to develop further programs of inquiry that go beyond the psychology of autonomy, programs that describe and explain the emergence of objectively different structures of control that are anchored in political–economic, legislative, and cultural factors (see Forbes and Jermier, 1995). This is important because so long as studies of workplace autonomy rely exclusively on micro thinking and psychological models, the politics of 'empowerment' in any given culture at any given time will probably be limited to regimes of illusory control.

The streams of research on workplace autonomy reviewed in this article all support the idea that being truly self-governing and free from excessive external control produce positive outcomes for individuals, groups, and work organizations. The more general thesis, that autonomy promotes human growth and development as well as positive health and well-being, is also supported. Autonomy sometimes is considered to be synonymous with individualism and egoistic willfulness but there is increasing evidence supporting the idea that collectivist autonomy is equally beneficial. The concept of workplace autonomy has received considerable attention from researchers in several traditions of study. While more research in each of the traditions is needed, a more pressing need is to begin integrating insights from all the traditions to develop a general theory of autonomy at work.

Workplace Deviance

Abstract

Workplace deviance is a serious and costly problem for organizations. This encyclopedia article outlines the growing body of scholarly research investigating these counterproductive workplace behaviors. Researchers have identified two main dimensions underlying deviant workplace behaviors. Numerous antecedents increase the likelihood and affect the target of workplace deviance. Multiple techniques deter, reduce, and/or prevent employees from participating in workplace deviance. However, these methods may come at great cost, whether financial or motivational. On the other hand, workplace deviance may sometimes be functional, for either employees and/or the organization. Proactive strategies are suggested.

For centuries, workplace deviance has been a serious issue for nearly all organizations (Case, 2000; Coffin, 2003) with prior research suggesting that the majority of employees (between 50 and 75%) have engaged in some type of deviant behavior (Bennett and Robinson, 2000; Harper, 1990; Harris and Ogbonna, 2002; Slora, 1991). The costs associated with workplace deviance have been estimated to be rather significant, with annual estimations being in the millions for US organizations (Case, 2000; Harris and Ogbonna, 2006). Workplace deviance is defined as "voluntary behavior that violates significant organizational norms and in so doing threatens the well-being of an organization, its members, or both" (Robinson and Bennett, 1995: p.556). Behaviors fitting this definition have also been referred to as counterproductive work behaviors (Fox and Spector, 1999), antisocial work behaviors (Giacalone and Greenberg, 1997), workplace aggression (Baron and Neuman, 1996; Folger and Baron, 1996), and organizational misbehavior (Vardi and Wiener, 1996).

Typology

The typology of workplace deviance developed by Robinson and Bennett (1995) used multidimensional scaling techniques to identify the underlying vast array of deviant workplace behaviors: (1) whether the potential harm was serious or minor and (2) the entity that was the target of the deviant act (employees or other individuals associated with the organization, such as customers and suppliers, which is referred to as *interpersonal deviance*, or the organization itself, which is referred to as *organizational deviance*). The overlap of the two orthogonal dimensions resulted in four different forms of workplace deviance. *Political deviance* involves minor deviant acts directed toward individuals at work, such as gossiping about coworkers; whereas, *personal aggression* entails serious deviant acts targeted toward individuals at work, such as sexual harassment. *Production deviance* refers to minor deviant acts aimed at the organization, such as leaving work early or arriving to work late; whereas, *property deviance* involves serious deviant acts targeted toward the organization, such as sabotaging equipment (Robinson and Bennett, 1995). Refer to Figure 1 for a complete overview of the typology, including examples of the four different types of workplace deviance.

Assessment

One of the earliest and most employed assessments for workplace deviance is Bennett and Robinson's (2000) Workplace Deviance scale, which consists of 19 items. This scale allows researchers to independently assess interpersonal deviance (intentional, potentially harmful behaviors that violate significant organizational norms and are directed at other individuals at work, which combines political deviance and personal aggression) and organizational deviance (intentional, potentially harmful behaviors that violate significant organizational

Figure 1 Typology of workplace deviance. Taken from Robinson, S.L., Bennett, R.J., 1995. The typology of deviant workplace behaviors: a multidimensional scaling study. Academy of Management Journal 38, 555–572.

norms and are directed at the organization itself, which combines property deviance and production deviance). For an overview of the Workplace Deviance scale refer to **Table 1**.

Another workplace deviance measure is the Counterproductive Work Behavior Checklist (CWB-C) that was developed by Paul Spector and his colleagues (Spector et al., 2006), which consists of 45 items which can be scored using two different formats. The first format replicates Bennett and Robinson's (2000) the two-factor structure of interpersonal deviance (referred to as CWB-P) and organizational deviance (referred to as CWB-O). The second format categorizes the 45 items into five dimensions: abuse, employee theft, sabotage, withdrawal, and production deviance. Additionally, Spector et al. (2006) constructed a shorter version of the original 45-item CWB-C measure. The shorter version of the CWB-C scale consisted of 32 items and had the ability to be scored using the same two different formats as the original 45 items scale.

Stewart and colleagues (Stewart et al., 2009) transformed Bennett and Robinson's (2000) Workplace Deviance scale into a nonself report measure of workplace deviance, which consists of 15 items and categorizes the items into interpersonal deviance (referred to as personal aggression) and organizational deviance, which can be further divided into production deviance and property deviance.

Meta-analyses of workplace deviance have confirmed that although interpersonal deviance and organizational deviance are highly correlated (Berry et al., 2007; Dalal, 2005), their differential relationships with important antecedents (e.g., personality traits) suggest that they are separate constructs and should be measured as such, especially if the research question calls for such a distinction. Berry et al.'s (2007) meta-analysis also suggested some differential effects in studies depending on which measure of workplace deviance was used (e.g., interpersonal or organizational deviance measures).

Table 1 Workplace deviance scale

Interpersonal deviance ($\alpha = 0.78$)
Made fun of someone at work.
Said something hurtful to someone at work.
Made an ethnic, religious, or racial remark at work.
Cursed at someone at work.
Played a mean prank on someone at work.
Acted rudely toward someone at work.
Publicly embarrassed someone at work.
Organizational deviance ($\alpha = 0.81$)
Taken property from work without permission.
Spent too much time fantasizing or daydreaming instead of working.
Falsified a receipt to get reimbursed for more money than you spent on business expenses.
Taken an additional or longer break than is acceptable at your workplace.
Come in late to work without permission.
Littered your work environment.
Neglected to follow your boss's instructions.
Intentionally worked slower than you could have worked.
Discussed confidential company information with an unauthorized person.
Used an illegal drug or consumed alcohol on the job.
Put little effort into your work.
Dragged out work in order to get overtime.

Reproduced from: Bennett, R.J., Robinson, S.L., 2000. Development of a measure of workplace deviance. Journal of Applied Psychology 85, 349–360.

Although these measures have been validated as measuring general workplace deviance, some studies have modified the measures to better represent a specific workplace deviance context for their specific research hypotheses. For instance, Darrat et al., 2010 created modified scales of organizational, interpersonal, and customer-directed deviance for outside sales' employees, Mitchell and Ambrose (2007) developed a measure for supervisor-directed deviance, and Posey et al. (2011) created deviance scales specifically for measuring computer abuse. Of course a plethora of measures for other individual deviant behaviors, such as theft, sabotage, and workplace incivility, already exist. The type of question being asked should predicate which measure is used.

History

Scholarly interest in workplace deviance has analytical roots dating back to the Industrial Revolution (Klotz and Buckley, 2013). Interpersonal deviance was first widely publicized during the eighteenth century when abusive supervision and harassment of employees was prominent in the workplace. Organizational deviance can be traced to the Luddite Rebellion during the nineteenth century, where employees destroyed machinery that replaced certain job functions.

Nonetheless, in spite of awareness and interest in employee misbehavior, and prior to the development of the broad bidimensional workplace deviance measure (Bennett and Robinson, 2000), empirical research on employee misbehavior involved analyzing only one or two specific counterproductive, antisocial, or deviant behaviors, such as employee theft (Greenberg, 1990), sexual harassment (Gutek, 1985), sabotage (Giacalone, 1990), absenteeism (Goodman and Atkins, 1984), withdrawal (Gupta and Jenkins, 1980), withholding effort or social loafing (Kidwell and Bennett, 1993; Latane et al., 1979), and soldiering (Taylor, 1903). Of course there is still a place for the study of individual deviant behaviors, such as with deviant behaviors involving national security information leaks, and consequently research continues to be done on individual antisocial behaviors. However, the broader focus on multiple behaviors that can be defined as 'harming the organization' allows researchers to investigate the common causes of such diverse organizational deviance behaviors as employee theft (Case, 2000), time banditry (Ketchen et al., 2008; Martin et al., 2010), and cyberloafing (Blau et al., 2006; Chidambaram and Tung, 2005; Lim, 2002). Considering these behaviors to have an underlying root cause provides theoretical integration as well as more efficient and productive research findings than studying individual deviant behaviors independently.

Potential Antecedents

Past research has investigated numerous situational, personal, environmental, and other factors in hopes of determining which strongly influence or predict workplace deviance. The main focus of workplace deviance antecedents appears to be situational or personal factors, with some studies integrating these two factors in conceptual models (e.g., Colbert et al.,

2004; Henle, 2005; Judge et al., 2006; Kantur, 2010; Skarlicki et al., 1999).

Situation-based Perspective

The situation-based perspective views workplace deviance as an outcome of organizational circumstances, actions, and/or treatment. For instance, abusive supervision (Tepper et al., 2001), boredom (Spector et al., 2006), group norms (Siehl, 1987), job (dis)satisfaction (Mangione and Quinn, 1975), and injustice perceptions (e.g., Colbert et al., 2004; Greenberg, 1990; Skarlicki and Folger, 1997), specifically interpersonal injustice (e.g., Ambrose et al., 2002; Colquitt et al., 2001; Flaherty and Moss, 2007; Henle, 2005; Judge et al., 2006) have all been identified as significant situational antecedents of workplace deviance.

Person-based Perspective

The person-based perspective infers an explanation for a person (or employee's) behavior from their personality, characteristics, or emotions rather than from situational or environmental factors. For instance, stress (Fox et al., 2001), negative emotions (Lee and Allen, 2002; Spector and Fox, 2002), negative affectivity (Richards and Schat, 2011), cognitive ability (Dilchert et al., 2007), low moral standards (Merriam, 1977), narcissism (Penney and Spector, 2002), age (Berry et al., 2007; Ng and Feldman, 2008), gender (Hershcovis et al., 2007), conscientiousness, and agreeableness (Mount et al., 2006; Salgado, 2002) have all been found to significantly impact workplace deviance.

Managing Workplace Deviance

There are several techniques managers and organizations can utilize to deter, reduce, or prevent employees from engaging in workplace deviance. The first thing organizations should do to help manage workplace deviance is to require the human resource department or hiring managers to screen applicants by having them complete a personality, cognitive ability, and/or integrity test since lower levels of cognitive ability (Dilchert et al., 2007), integrity (Lucas and Friedrich, 2005), conscientiousness, and agreeableness (Mount et al., 2006; Salgado, 2002) have been associated with workplace deviance. Another good screening method is to have the applicant sign a release form allowing the organization to contact the applicants' former employer(s) and professional reference(s) to identify past work ethic, attitudes, and antisocial behaviors in the workplace.

After the screening process, organizations can continue to manage workplace deviance by implementing different policies, strategies, and courses of actions. For instance, organizations can ensure employees are not wasting valuable work time and effort by monitoring employees electronically, such as by screening their e-mails, histories of internet browsing, and individual key strokes (Klotz and Buckley, 2013). Organizations can also attempt to decrease or abolish workplace deviance by engaging in different strategies, such as enhancing employee and supervisor training, employer–employee relations, communications, and perceptions of organizational justice. Additionally, organizations can adopt policies which discourage or prohibit employees from participating in certain deviant behaviors, such as writing unflattering or damaging information on social media web sites, by stating they will terminate employment for policy violators. However, in order for the organization or manager to be considered fair (and to enhance organizational justice perceptions), the consequences should match the seriousness of the deviant behavior (Robinson and Bennett, 1995). For instance, serious deviant acts (such as, stealing from the organization or sexual harassment) should have similarly stringent consequences and they should be harsher than those given for minor deviant acts (such as, leaving work early or gossiping about coworkers). Punishments should also be delivered in private, consistently, and according to the established organizational process (Bennett, 1998).

Although organizations may desire to reduce or eliminate workplace deviance, these techniques come with several costs. For instance, the financial costs associated with having job applicants complete various screening tests (e.g., personality and integrity tests) are notable, especially if there are many applicants to screen. Therefore, organizations need to identify whether the specific technique is cost efficient and will significantly reduce workplace deviance such that the costs associated with implementing the technique are less than the costs associated with workplace deviance (Levy and Tziner, 2011). Otherwise, when the costs associated with workplace deviance are less than the costs associated with the technique, the organization should choose a different technique that produces a better cost–benefit analysis. Additionally, some techniques (e.g., electronically monitoring employees) may lower employee morale, loyalty, organizational trust and commitment, while increasing aggression, job dissatisfaction, and other undesirable attitudes or behaviors, which may potentially increase workplace deviance.

Recommendations

Organizations should be wary of the techniques they use to manage workplace deviance, especially since most employees believe they are 'entitled' to privacy (e.g., to not being monitored) or have the right to behave deviantly to some extent (Klotz and Buckley, 2013). Organizations and their managers should be advised that the costs associated with some techniques (e.g., cameras and other monitoring equipment) may actually outweigh the costs associated with workplace deviance (e.g., a few lost moments due to an employee surfing an unauthorized web site), not to mention the impact the technique may have on employee attitudes and behaviors. For instance, employee monitoring has been shown to occasionally backfire and to result in increased levels of workplace deviance because of employees' reactance to the perceived privacy invasion and the sense of being controlled (Posey et al., 2011). Additionally, when punishments for engaging in deviant behaviors are imposed, organizations and managers should put forth effort to ensure they are fair and match the severity of the deviant act. It is probably better to be proactive in creating an organizational culture which offers employees respect, fair processes, just pay, meaningful work, autonomy, and involvement, factors which are related to reduced levels of

counterproductive workplace behavior, rather than to be reactive in responding punitively to observed employee aggression.

Organizations should also be aware of the possibility that workplace deviance may have functional outcomes for employees and organizations (Robinson and Bennett, 1995). For instance, employees may be able to relieve stress or tension by engaging in certain deviant behaviors (Klotz and Buckley, 2013; Krischer et al., 2010; Robinson and Bennett, 1995), such as using work time to make personal phone calls to ensure a family member's well-being, thereby allowing them the ability to focus more on their job and thus, increase performance. Additional examples of 'functional' deviance may include employee gossip assisting in establishing workplace norms, rule-breaking leading to innovative processes and improved efficiency, and employee conflict or harassment (such as abusive supervision) causing functional turnover. Additionally, more noticeable deviant acts (e.g., theft or sabotage) may provide warning signs to organizations and managers that employees are likely to engage in additional and possibly more severe deviant acts and thereby giving the organization an opportunity to identify and implement different techniques to reduce or eliminate these deviant behaviors before they increase or escalate.

Conclusion

Workplace deviance is a serious and costly problem for organizations. There are numerous variables that increase the likelihood of employees engaging in deviant behaviors. Therefore, managers should be aware of the selection tools that might restrict those prone to deviant behaviors from joining the organization. Managers should also be aware of their own behaviors (e.g., monitoring or bullying) that may provoke employees to behave deviantly, especially since most employees already believe they are 'entitled' to participate in deviant behaviors to some extent. There are multiple techniques that organizations and managers can use to deter, reduce, or abolish workplace deviance. However, these methods may come at a price, whether it is monetary or at the expense of valuable employee attitudes, such as loyalty and trust. Additionally, even though organizations attempt to minimize or eliminate these deviant behaviors, some of them may prove useful and productive for employees and organizations. The best strategy is probably to develop an organizational culture based on fairness, mutual respect, employee involvement, and autonomy. All of these factors have been shown to be related to lower levels of workplace deviance.

Abstract

Workplace safety and health refers here to all practical actions taken at the shop floor level to promote the safety and health of workers. Such actions should be theory driven because accident theories help to pinpoint dangerous factors in the company, and they offer directions for practical solutions. The focus of these actions is the behavior and attitudes of the workers subject to the highest risk of occupational accidents and diseases.

Definition of Workplace Safety and Health

Workplace safety and health refers here to all practical actions taken at the shop floor level to promote the safety and health of workers. Such actions should be theory driven because accident theories help to pinpoint dangerous factors in the company, and they offer directions for practical solutions. The focus of these actions is the behavior and attitudes of the workers subject to the highest risk of occupational accidents and diseases.

Short History of Occupational Safety and Health

The history of occupational safety and health starts in the fourth century BC, when Hippocrates described the occurrence of lead poisoning among miners. Later, another Roman physician, Galen, wrote about various occupational diseases (Fraser, 1989). However, the first written source to mention a disease as actually being occupational in origin was Agricola's *De Re Metallica* (1556), which ends with a note on diseases and accidents among miners. At that time one woman could be married to as many as seven miners, one after the other. Eleven years later (1567) Paracelsus published *Von der Bergsucht und anderen Bergkrankheiten*, describing the diseases of smelter workers and metallurgists.

Finally, in 1700, Ramazzini published a book entitled *De Morbis Artificum Diatriba*, in which he examined the health conditions of workers in over 50 occupations. Because of his success, he is called the father of occupational medicine (Carnevale et al., 2012).

Observations on occupational diseases did not lead to legislative action until 1802, when the Health and Morals of Apprentices Act was confirmed in England. This act was then improved by the Factory Acts in the middle of the nineteenth century. The first compulsory social security system for wage earners was also set up about that time, in Germany in 1883. The Workmen's Compensation Act followed in Britain in 1897 providing for automatic compensation to an injured worker. In 1919 occupational safety and health became a truly worldwide concern when the International Labor Organization was founded in Geneva to establish International Conventions and International Recommendations for the development of standards and procedures for occupational health and accident prevention (Fraser, 1989).

Theories on Occupational Accidents

A feature common to different definitions of an occupational accident is the unexpected and unintentional nature of the incident. When physical injury is added, an occupational accident can be defined as an unexpected and unintentional series of events leading to the physical injury of a person at work. The other precondition for an occupational accident is a contractual relationship between the employer and the employee (Figlio, 1985).

Until the end of the nineteenth century people thought that accidents were brought on by their sins or were 'God's will.' This idea was based on the fact that most hazards were caused by natural phenomena. People had very limited means with which to resist the forces of nature. The onset of industrialization in the twentieth century meant that production moved from homes to factories. Since people had built these environments, most of the hazards were also man-made. Thus the idea of accident prevention fell on fruitful ground.

Theories on Accident Causes

The first scientific theory attempting to explain accidents was the theory of accident proneness. Greenwood and Woods (1919) insisted that 'accidents occur to a limited number of individuals who have a special susceptibility to accidents' (preface). Accident proneness was presumed to be a stable personality trait. The theory assumed that some people have an inherent tendency to be involved in accidents. The need for the term 'accident proneness' was so strong that it was independently found both in England (accident proneness) and in Germany (Unfallneigung) (Burnham, 2008).

The theory of accident proneness has been criticized on both theoretical and empirical grounds. The studies published have displayed conceptual confusion surrounding the meaning of accident proneness. Accident proneness is understood as a unitary trait, as a general characteristic, and as an innate and unmodifiable characteristic, and it is thus used as an explanatory concept. The statistical criticism of the accident proneness theory culminates in the question of whether the entire population has the same risk to be involved in an accident or not. Because the accident proneness theory is based on an incorrect assumption of homogeneous exposure to risk, it should be substituted by the concept of accident liability, which is based on the assumption of the inequality of exposure. Also the

personnel selection method based on the accident proneness has been ineffective and showed a review of 26 studies (Guastello, 1993).

According to the danger factor theory, an accident happens when a worker and a danger factor meet so that the worker injures himself or herself. The accident is a stochastic event, the probability of which is determined by the number of danger factors. The most critical danger factors are those with the highest energy content (Skiba, 1973). This theory is mostly based on practical experience.

A more sophisticated version of the danger factor theory is the ergonomic approach to the causes of accidents. The ergonomic approach assumes that disturbances in the flow of information increase the risk of accident occurrence. The exchange of information between a worker and his or her environment or between a worker and coworkers or supervisors is a precondition to accident avoidance (Saari, 1984).

According to deviance theory (Kjellén, 1984), a chain of events leading to an accident starts, when in the production process happens something which deviates from the normal process. In the concluding phase, the loss-of-control of the production system and the inadvertent release energy are activated. In the injury phase body starts to absorb energy, which is nearby the danger factor theory.

The normal accident theory assumes that accidents are inevitable or 'normal' in some types of technological systems (Perrow, 1984). Accidents generally begin with failures of one or more lower level components of the organization. Then they escalate to higher levels of organization. The examples of this kind 'normal' accident come from nuclear power industry.

A sociological theory of occupational injuries insisted that injuries are produced by social relations of work. The theory assumes that social relations at workplace generated errors, which lead to occupational injuries. Increased autocontrol of workers and management involvement in safety are the means to prevent occupational injuries (Dwyer, 1991).

The Berkeley group from the University of California studied safety in the high reliability industries like air traffic control systems, nuclear power plants, and submarines. They are complex technological systems that put a high premium on reliability because their operating environments seldom offer them a second chance. The high reliability theory emphasizes the following conditions as being necessary, but not sufficient, for ensuring reliability: a strategic prioritization of safety, careful attention to design and procedures, a limited degree of trial and error learning, redundancy, decentralized decision making, continuous training often through simulation, and strong cultures that encourage vigilance and responsiveness to potential accidents (Weick et al., 1999).

Comparing these two theories, Shrivastava et al. (2009) have insisted that theories look at the same phenomenon from different points of time. High reliability theory asserts that accidents are avoidable if the organizations take enough pains to make workplace safe. Thus accident-free environments are possible in the long run. Normal accident theory holds accidents in complex and tightly coupled system inevitable. Accidents can occur at every minute in the organization.

The latest theory of occupational injuries is the resilience theory starting from environmental sciences. The theory stressed the organization's ability to anticipate and avoid unpredictable challenges. A resilient organization is flexible in such a way that operations can return to the normal process with only minimum damage. Occupational injuries are according to resilience theory due the variation of human performance. When the human performance cannot stabilize, the technology should build such as allowing a person to make mistakes (Hollnagel et al., 2006).

Theories on Risk Taking

The recent theories related to accidents are those on risk taking. They have been developed in research on traffic safety. Most of the authors have thought that their theories can be applied to risk-taking situations in work life as well.

The risk compensation theory assumes that people have a constant level of risk that they are ready to accept. If the risk level decreases due to safety measures (e.g., seat belts in cars), people tend to adjust their goals (e.g., try to arrive sooner at their destination) so that the risk level returns to exactly the same level as before. The effects of safety measures are thus eliminated in the long run (O'Neill, 1977). Because the assumption of exact compensation is criticized, the concept of risk compensation is often replaced by the concept of behavioral adaptation.

According to the risk homeostasis theory, the risk of traffic accidents is determined by the homeostatic system, which is analogous to the room temperature system. The main assumption of the theory is that the target level of risk is the only factor determining accident rates. Perceived benefits and costs of risk taking and cautious behavior are the factors controlling the level of target risk. The risk homeostasis theory argues that the effect of a safety measure depends on its motivational nature for the people who use it. The effect of a measure (e.g., mandatory seat belt use), which does not motivate its users will be eliminated in the long run as the drivers take more risks. However, safety can be enhanced by measures that motivate people to desire safety (Wilde, 1982). If such motivation can be achieved, the effect of the measure may be greater than what technical calculations show.

A complementary theory for the risk homeostasis theory is the risk motivation theory (Trimpop, 1994). This model assumes that both personality and situational factors influence one's risk perception, which is divided into physiological, emotional, and cognitive components. Each one has its own target level of risk, which contributes to the total target level of risk. Based on the rational calculation of costs and benefits, a risk taker is motivated to act. These acts influence the environment, which then gives either positive or negative feedback. The actor can then perceive the risks in a new and better way.

The theory of zero risk received its name from the assumption that drivers of motor vehicles adapt to the risks involved in driving to the point that they do not generally feel any risk in a traffic situation or their subjective risk assessments approach zero. People avoid the feeling of risk just as they avoid pain. There is a risk threshold, however, above which risk is experienced as aversive. A driver tends to satisfy his or her motives in traffic, as well as in other areas of life. This need to satisfy motives pushes him or her to drive faster and more hazardously. Both excitatory and inhibitory motives influence

the decision making of a driver. The most hazardous excitatory motives are 'extra motives' (i.e., those outside traffic, such as the saving of time and effort) which prompt the driver to increase speed. The increased risk of an accident is related to the strength of these extra motives (Näätänen and Summala, 1976).

If the psychological portrayal of a human being with respect to accident theories is analyzed, a change can be seen. The first theories assumed that a human being is a passive accident victim who has an inherent tendency to be involved in accidents. In the more recent theories, a human being is an actor who actively searches for information from the environment. The theories, however, accept that a human being is not perfect and does make mistakes and errors. As technology becomes more reliable, a human being will be the greatest risk factor for himself or herself.

The Behavior Modification Approach

The approach of behavior modification is based on an operant learning behavior. Behavior is seen as a function of its relation to various prior and current events. The preceding events are called antecedents, and the events following the performance are consequences. If an act has increased in rate after a particular consequence has reliably followed it, the consequence is reinforcing. But if the rate has decreased, the consequence is aversive. Lastly, if a behavior disappears when a prior reinforcing consequence is continued, the situation is called extinction (Sulzer-Azaroff et al., 1994).

Interventions

The training of workers is usually the first form of intervention included in a behavior modification program. The aim of training is to teach safe work habits. The training must be as illustrative as possible, for example, showing photographs of workers using safety glasses. It is also possible to show unsafe scenes and ask workers to point out the unsafe actions. The important point in training is to repeat the safe habits in different ways for the workers. Several studies, however, have shown that training alone is not sufficient to improve safety performance (Sulzer-Azaroff et al., 1994).

The alternative method for traditional classroom teaching is an informational safety campaign. The first prerequisite for an effective informational campaign is to set a clear objective with a specific message that is positive, simple, plausible, and comprehensible. The campaign material should be designed to attract attention. Posters should be placed at crucial points of action, for example, on the wall of the canteen at a construction site. The effect of a campaign is usually short-lived. The types of intervention used in informational safety campaigns have not influenced the number or the seriousness of accidents.

The other alternative method is to utilize small groups in accident prevention. This idea is based on experiences from quality circles, which are problem-solving groups largely used in the manufacturing industry. As in the case of quality circles, small accident prevention groups consist of members of the same organization meeting regularly to solve safety-related problems. In a Finnish shipyard the small groups had from 4 to 13 members, and they met 5–11 times during 1 year. The two tasks of the groups were to eliminate the obstacles to good order and safety and establish new housekeeping practices – behavior modification. The program was successful both in improving housekeeping and in reducing accidents (Saarela, 1990).

Based on a social psychological approach, a discussion method was used in one Finnish company to reduce work-related traffic accidents. Every team had three sessions: in the first one, drivers gathered problems related to driving during work hours. These problems were gathered to a report and based on it, drivers made suggestions to solve these problems on the second round. In the third round, drivers made decisions on commitments to change their driving behavior. Then drivers wrote down the common decision, signed it and put the paper in their own pocket. After this process the number of traffic-related accidents decreased significantly by 72% (Salminen, 2008).

Goal setting is the other main method to improve performance. The first requirement for successful goal setting is that the workers who are the subjects of the intervention participate in the setting of the goals. Difficult goals inspire better performance than easy goals do. The best goals are difficult, but achievable. The utmost goal should be divided into subgoals that are easy to understand. The first goals should be rather concrete, such as 'we should use hard hats all the time at the construction site' (Locke and Latham, 1990).

Positive Reinforcement

Positive reinforcement refers to an increase in the frequency of a response following the presentation of a positive reinforcer. Whether or not a particular event is a positive reinforcer is determined empirically. The effectiveness of the reinforcer depends on several factors. Reinforcement given immediately after the response is more effective than the feedback given after a long delay. The greater the amount of a reinforcer contributes, the more frequent the response presents. Reinforcers that are highly valued lead to greater performance. A continuous schedule of reinforcement, where a response is reinforced each time it occurs, is the most effective (Kazdin, 1975).

Positive reinforcement should be given soon after the observation of a desired behavior. It ought to be given regularly, for example, once a week. The feedback should be visible and given to all workers at the same time. One way to fulfill these requirements is to place a special information board on the wall so that a curve illustrates the development of the safety score on the experimental area from one observation to another. One example of such an information board is the TUTTAVA-board developed at the Finnish Institute of Occupational Health (**Figure 1**), TUTTAVA being a Finnish acronym for a program to help improve production, quality, and safety.

One form of positive reinforcement is the use of a token economy. A token is a tangible object, for example, a lottery ticket, which can become a conditioned reinforcer. The use of tokens may shorten the delay between the behavior and the consequence, reinforce the behavior any time and any place, and provide a visible record for evaluation. The weakness of the token economy is that it pictures behavior as a simple series of stimuli and reactions. The token economy is, however, rather inexpensive for companies to operate (Brown, 1978).

Figure 1 TUTTAVA information board.

Measurement of Safety Behavior

It is useful to start a behavior modification program with accident analysis. The analysis of accidents during the previous 3–5 years pinpoints the hazardous sites of the workplace. It is worthwhile classifying accidents as unpreventable and preventable, that is, as whether or not workers could avoid a similar accident if they changed their behavior. The researcher should then discuss the actions that could prevent accidents with the on-site personnel. Using the results of this analysis, the researcher collects 10–20 safety practices that should be phrased positively (Komaki, 1986).

The next step is to prepare the measurement of safety performance. Generally an observation method is used for this purpose because the object of measurement is the external behavior of the subjects. The researchers should select observation periods at random. When the observation is done at different times of the day, the workers behave normally and do not avoid the most hazardous tasks. The observation can be done from a single observation point or by walking through the observation area; the latter method is more common.

The observation sheet includes, at a minimum, a list of the desired safety practices. Usually it is constructed with only a dichotomized classification. The behavior of the observed worker is either safe or unsafe, as defined by the criterion of behavior included in the observation sheet. The third possible category is 'not observed,' under which the practice does not occur (Komaki, 1986).

One example of an observation method is ELMERI, ELMERI being the Finnish acronym for a workplace safety and health observation method. It has been developed through cooperation with safety authorities, safety managers, and safety representatives from selected workplaces. The observation method consists of 26 items, divided into 7 groups: (1) safety behavior, (2) order and tidiness, (3) machine safety, (4) industrial hygiene, (5) ergonomics, (6) walkways, and (7) first aid and fire safety. For each item, the observer makes a decision as to whether the item is correct according to the safety criteria defined in the handbook of the observation method. The alternatives for the observer are 'correct,' 'not correct,' or 'not observed.' The 'not observed' alternative is used, for example, when there are no machines with permanent means of access in the workplace. It takes about 15 min to observe one workstation with the ELMERI method, and only a few hours of training are needed to reach an acceptable level of interobserver reliability. It has been shown that a high safety index from ELMERI is related to a low accident rate (Laitinen et al., 1998).

The walkthrough observation rounds should be repeated once a week during 5–10 weeks. The suggested time for each round is 30–60 min. The minimum number of observations during one observation round is 100. The results of the observations are calculated as a safety score as follows:

$$\text{safety score} = \text{correct}/(\text{correct} + \text{not correct}) \times 100.$$

The higher the value of the safety score, the better the safety situation within the workplace (Komaki, 1986).

The reliability of the observation is based on the interobserver agreement. Therefore, two observers should independently assess the behavior of the same workers. It is desirable to conduct reliability checks when both the observers and the observed workers are unaware that checks are being conducted. The reliability is calculated by dividing the smaller frequency by the bigger frequency and multiplying by 100. The reliability should be at least 80% to be acceptable (Kazdin, 1975).

Experimental Designs

The effect of the intervention is demonstrated by the experimental design. It has two tasks. First, it should show that the change in behavior is permanent. Second, it should prove that

the change in behavior is due to the intervention. There are three main types of experimental designs.

Reversal or ABAB Design

The reversal design demonstrates the effect of the intervention by alternating the presentation and removal of the program over time. The purpose of the design is to demonstrate a functional relationship between the target behavior and the intervention. The first task in a reversal design is to measure the baseline rate of behavior, which describes the behavior in a normal situation before the intervention. The baseline period (referred to as phase A) is continued until the rate of the response becomes stable.

Then, in the experimental phase (referred to as phase B), the intervention is carried out. This phase continues until the behavior reaches a stable level or diverges clearly from the baseline level. Now the change in behavior is evident, but the cause of change is unclear.

In the reversal phase (phase A) the intervention is withdrawn. The target behavior usually returns to or near the original baseline level. The purpose of the reversal phase is to determine whether the behavior would have remained unchanged if the intervention had not been introduced. When the behavior reverts to the baseline, it is possible to reinstate the intervention (phase B). The design is called the ABAB design because the phases A and B are alternated (Kazdin, 1975).

Control Group Design

Another way to demonstrate the effect of intervention is the classical experimental design with experimental and control groups. The intervention is done with one group (the experimental group) and not done with the other group (the control group). Immediately before and after the intervention the behavior of the workers is assessed. The basic requirement of the study design is the similarity of the groups. The best procedure to control for systematic differences between the groups is to allocate the workers to groups at random (Kazdin, 1975).

At the shop floor level, a random classification of workers is not always possible for production reasons. Then two departments, which are as similar as possible, are selected as experimental and control groups. In addition to nonrandomness, overlapping of the information between the departments may be a problem in the comparison of departments.

Multiple-Baseline Design

The third experimental design to show the effect of interventions is the multiple-baseline design. The aim of this design is to demonstrate that the change in behavior is associated with the introduction of the contingency at different time points. This design requires the use of two or more interventions. After the baseline reaches a stable rate, one of the interventions is introduced, while baseline conditions are continued for other interventions. When the rates are stable once again, the second intervention is introduced. The effects of each intervention are established only after it has been introduced.

One problem that can occur with the multiple-baseline design is that changes in behavior take place too early. If behavior changes before the intervention are introduced, it is not clear whether the intervention is responsible for the changes or not (Kazdin, 1975). Another problem is that the effects of the different interventions could be confused.

Analysis of Intervention Data

Intervention studies often require the use of statistical tests appropriate for single-case experimental designs. Conventional t and F tests can be used in the statistical analysis of intervention data if the data are not serially dependent. This practice requires that the autocorrelation (i.e., correlation between data points separated by different time intervals) not be significant. The other statistical method is to use tests for time series. The best for a short time series ($n < 10$) is Kendall's tau, which analyzes the mean trend.

It is possible to complement the quantitative data of the effects of the intervention study by qualitative data. Qualitative methods are the most useful for analyzing the meanings and symbols of the culture or subculture. In an intervention study, the most useful qualitative method is perhaps a discourse analysis. With this method, a researcher can analyze the possible change in the attitudes of the workers participating in the intervention.

In the reports of behavior modification studies, graphs should be used to illustrate both the study design and the results. It is easy to show the development of a safety score with a line graph. In some cases, it is possible to use the same graph to give feedback to workers and to illustrate the results in the report.

High-quality intervention studies help to avoid the wasting of time, money, and effort. Shannon et al. (1999) have presented eight criteria for an intervention study of high quality. First, the objectives of the study or its underlying hypotheses are clearly presented. In the experimental design, the subjects are randomly allocated to experimental and control groups. The study has external validity and therefore its results can be generalized to other workplaces. The outcome measurement with acceptable reliability and validity should be appropriate to the objective of the intervention. Qualitative data can be used to supplement quantitative data. Diffusion of intervention manipulation from the experimental group to the control group (overlapping) or improper randomization is the main threat to internal validity. Appropriate statistical analysis should be applied in the analysis of the data set. The conclusions should address the program objectives and the limitations of the study and be supported by the analysis. These criteria are useful both in the assessment of other studies and in the planning of one's own study.

Future Recommendations for Workplace Safety and Health

The fatality rate in Finland has decreased from 7.2 to 1.2 deaths per 100 000 workers from 1975 to 2009 (Statistics Finland, 2009). Most of this positive development is due to technical solutions to prevention and improved safety inspections. Nowadays, most of the technical solutions are in use and simple accidents can be prevented. Only the more complex

accidents need to be tackled; they are due to the interaction between technical failure and human error.

Occupational accidents cause disturbances in production. When a serious accident occurs, all workers stop their work and go to help. According to Finnish calculations of accident costs, this participation forms the highest costs to the employer. Some customers therefore demand that the number of occupational accidents should stay under the acceptable limit.

Traffic research in Sweden has produced an idea called Vision Zero. According to this idea, no one should be killed or sustain an injury resulting in permanent impairment. Some workplaces, at least in Finland, have already accepted the idea of Vision Zero. In other words, they follow the principle that no accident is acceptable and that all accidents are preventable. The zero accident forum is a voluntary-based community of the companies, which wanted to reduce their accidents. In the forum sessions and intranet they can change their experiences about the accident prevention and pick up the best practices.

In the European Union, national legislation on workplace safety is based on Framework Directive 89/391/EEC. The implementation of the national legislation has been rather successful in the Finnish workplaces. Another successful example is the Occupational Safety System in Germany, through which stakeholders can provide preventive services.

These trends increase the expectations for safety modification behavior. Workplaces require more effective ways of changing the attitudes of workers to a more positive direction and activating them toward work safety. On the other hand, a deeper understanding of human behavior based on the advances of social and behavioral sciences makes it possible to respond to these increased requirements.

Workplace Stress

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article defines workplace stress and discusses major historical models for explaining stress, namely the Institute for Social Research model and the job demands–control model. Next, we discuss contemporary theories of workplace stress, including conservation of resources, job demands–resources, and the effort–reward imbalance model, followed by a discussion of primary, secondary, and tertiary workplace interventions. We continue by examining contemporary issues and advances in stress research. Finally, we conclude by calling for future research in several highlighted areas, such as technology-related stressors, diversity, and eustress.

Stress is one of the most universal experiences in the workplace. In fact, it is such a pervasive issue that for decades, a large portion of workplace research has consistently been dedicated to investigating the antecedents and consequences of workplace stress. Despite this volume of literature, the term 'stress' is still often misused in both research and colloquial contexts. At its core, workplace stress can refer to the overall process by which employees are met with demands, and their subsequent physical, cognitive, and emotional reactions to those demands. The demands, themselves, are correctly referred to as stressors, whereas the outcomes of, or reactions to, the stressors are correctly referred to as strains. A variety of workplace stressors have been heavily investigated, including workload, role conflict, role ambiguity, organizational constraints, interpersonal conflict, and time pressure, to name a few. Similarly, research has investigated a host of strain outcomes, including burnout, physical symptoms/health (e.g., illness; back pain), disengagement, withdrawal, depression, and other well-being variables.

The extant literature has generally made a compelling case that workplace stressors can not only impact individuals through strain outcomes, but also organizational effectiveness (such as individual and group performance, absenteeism, and turnover). Given the negative impact of the stressor–strain process in the workplace, researchers have endeavored to create theoretical models to determine how this process operates, as well as to determine aspects of the individual and the workplace that could potentially exacerbate or buffer the impact of workplace stressors. In this article, we will briefly describe two historical models of workplace stress, followed by discussing three contemporary models. Next, we describe work conducted on workplace stress interventions, and finish by discussing contemporary issues in workplace stress research and areas for future research.

Historical Models of Workplace Stress

ISR Model

Though several general models of stress were proposed in the mid-1900s (e.g., General Adaptation Theory; Selye, 1956), workplace stress was not explicitly investigated until the 1960s and 1970s. Perhaps the first stress model that explicitly investigated stress in the workplace originated from the University of Michigan's Institute for Social Research (ISR), and therefore became known as the ISR model (French and Kahn, 1962; Kahn and Byosiere, 1992). The ISR model is inclusive, and consists of several steps or factors that could potentially impact a person's experience of stress at work. The first step involves aspects of the objective work environment and broadly contains anything in an employee's surroundings that could be considered a stressor. Temperature, noise, hours worked, number of coworkers, physical space, and similar environmental factors would be encompassed by the first step of the ISR model.

The second step concerns the psychological environment – that is, how an employee *perceives* the objective workplace environment. This perception dictates whether environmental variables are perceived as 'threatening', or as a stressor, and leads to immediate cognitive, behavioral, or physiological activation. This activation, over time, can result in employee strain outcomes (e.g., burnout, depression) and other negative effects, such as reduced performance and withdrawal. The ISR model recognizes that perception of stressors are not unilateral across all people, and hence takes into account individual differences, including demography, personality, and quality of interpersonal relations. Any of these factors could impact this model at any point, including initial perception of the stressors, immediate reactions to the stressors, and long-term effects of these reactions.

The ISR model has not been empirically tested, but rather has served as an important guide for researchers interested in stress. The influence of the ISR model can be seen in other older stress models (job demands–control (JDC); facet model; Beehr and Newman, 1978), as well as in contemporary models of stress (e.g., job demands–resources (JD-R)). This model, therefore, laid an important groundwork for further theoretical development of workplace stress models.

JDC Model

A second model that played a major role in the development of modern workplace stress theories is the JDC model (Karasek, 1979). The JDC model distinguished two elements of the work environment to explain job strain. Job demands refer to the taxing aspects of work whereas job control taps into the discretion individuals have over job-related decision making.

Individuals experience strain when facing a combination of high job demands and low job control (strain hypothesis). On the contrary, when high job demands are matched by a high level of job control, people feel activated at work (learning hypothesis). The buffer hypothesis was later derived from the JDC model and states that job control can buffer the negative effect of high job demands (Van der Doef and Maes, 1999). The model was later expanded into the job demands–control–support (JDCS) model by taking into consideration the important role of support (Johnson and Hall, 1988). Accordingly, the buffer hypothesis is concerned with the synergistic effects of high control combined with high support. Historically, the JDCS model has been perhaps the most influential model in job stress research, though it is not without limitations. For instance, although considerable empirical support was found for the strain hypothesis, the buffer hypothesis has received limited empirical support (Van der Doef and Maes, 1999). The empirical support for the buffering effect of control in the JDC model is mainly limited to cross-sectional studies that measured job demands and job control at a comparable level of specificity. The synergistic moderating effect of job control and support, as stated in the JDCS model was largely unsupported. Moreover, the model was also criticized for neglecting other important facets of the work environment (Bakker and Demerouti, 2007).

Contemporary Models of Stress

Across the past 20 or so years, there have been major advances in theoretical models designed to better explain occupational health. Though a discussion of all models is beyond the scope of this article, we will elaborate upon three of the most-researched models: effort–reward imbalance (ERI), conservation of resources (COR), and JD-R.

ERI Model

A first contemporary theory used in the workplace stress literature is the ERI model, which has gained popularity in recent years, particularly in Europe. Originally established in sociological-medical literature (Siegrist et al., 1986), the ERI model takes into account the relationship between efforts and rewards associated with the workplace. Efforts are actions taken to respond to workplace demands – both stressors and obligations – and rewards represent benefits distributed by the organization, including money, promotion opportunities, belonging, and esteem/appreciation. The ERI posits that individuals evaluate the rewards they receive in exchange for their efforts to determine whether the rewards are sufficient. A long-term imbalance in the effort–rewards relationship – where work, in general, is characterized by high effort and low rewards – might cause strain reactions, such as burnout and physical symptoms. Furthermore, commitment is thought to impact the strain outcomes of this imbalance, where people who are highly committed (or 'overcommitted') to the job will experience worse strain outcomes than those who are less committed.

The ERI model shares many of the characteristics of Equity Theory (Adams, 1965), which also posits that employee effort (inputs) should match rewards (outputs). However, Equity Theory has primarily been applied in order to explain employee behaviors, such as counterproductive work behaviors, whereas the ERI model – originating from a medical tradition – has been primarily focused on explaining health-related outcomes, particularly objectively measured strains. Indeed, imbalances in the effort/reward ratio, where efforts exceed rewards, have been linked in numerous studies to cardiovascular incidences, cardiovascular risk symptoms (e.g., hypertension; cholesterol), sickness absence, unhealthy behaviors (e.g., smoking cigarettes and drinking alcohol), and mental health (depression and burnout). The most frequently recognized limitation of the ERI model is that the effort–reward balance/imbalance is assessed using a scale that assesses a ratio between these factors, and is therefore difficult to evaluate from a psychometric perspective (though efforts have been made to address this concern; see Siegrist et al., 2004). For the most recent review of the literature on the ERI model, see Van Vegchel et al. (2005).

Conservation of Resources

The COR theory takes an ecological approach to stress research by incorporating environmental and internal processes into the concept of resources (Hobfoll, 1989, 2001). Resources refer to elements that are valued by individuals or factors that are instrumental for attaining the valued elements. They can be delineated into objects (e.g., food), personal characteristics (e.g., sense of humor), conditions or states (e.g., marriage), or energy resources (e.g., time). The fundamental tenet of COR theory is that individuals are motivated to obtain, retain, protect, and foster their resources. Accordingly, psychological strain will occur: (1) when resources are threatened, (2) when resources are lost, or (3) when individuals fail to gain resource return proportionate to their resource investment. Moreover, individuals are more sensitive to resource loss than resource gain. Individuals will need to invest resources in order to cope with threatened or actual resource loss and to reap resources. Therefore, people with fewer resources are less able to invest their resources and more prone to strain, leading to a resource loss spiral and the adoption of a defensive strategy to protect their resources. On the contrary, people with more resources are more likely to focus on protecting their resources and attaining more resources, thus resulting in a resource gain spiral.

In comparison to other job stress models, the COR theory offers a comprehensive account of stress by taking into account both contextual and self-related resources. Moreover, the COR theory also gives explicit explanations for the conditions that could lead to and result from stress, thus rendering a more dynamic perspective in stress research. As such, the theory has been applied to and supported by stress studies ranging from traumatic stressful events to chronic job stressors (Hobfoll, 2001; Hobfoll and Shirom, 1993). Although sometimes criticized for being too general in terms of conceptualization and theorization (Hobfoll, 2001), the COR theory will continue to provide unique insights into workplace stress research.

Job Demands–Resources

The JD-R model (Demerouti et al., 2001) contends that job aspects fall into two general categories (i.e., job demands and

job resources) and provides a parsimonious model to explain workplace stress. Specifically, job demands refer to the physical, psychological, social, or organizational characteristics of the job that take substantial physical and/or psychological efforts to address at the expense of physical and/or psychological costs. Common examples of job demands include work overload and role conflict. Job resources refer to the physical, psychological, social, or organizational aspects of the job that are instrumental for work goal achievement, promote personal learning and growth, and/or reduce job demands and their associated negative impacts. Examples of job resources include coworker support and job autonomy.

The JD-R model elaborated on the JDC model by classifying a broad range of job characteristics into two overarching categories (Bakker and Demerouti, 2007), presumed to impact both employee strain and beneficial outcomes (e.g., engagement). Coping with job demands can exhaust one's energies and result in resource depletion, a mechanism similar to the well-established stressor–strain relationship. This mechanism is the health impairment or energetic process of the JD-R model. Job resources, due to their motivational nature, can lead to higher levels of engagement at work, thus activating a motivational process. In addition to the main effects of job demands and job resources, it was further proposed that job resources could buffer the negative impact of job demands, which is similar to the buffering effects of job control and support in the JDC model (Bakker and Demerouti, 2007).

More recently, the importance of personal resources has received increasing attention in the JD-R model (Schaufeli and Taris, 2014). Personal resources refer to the psychological characteristics that are associated with one's resiliency and perceived capability to exert control and impact the environment, including factors such as attribution style, hardy personality traits, and self-efficacy, among others. The idea behind this expansion of the JD-R model is that personal resources could influence the way people perceive job characteristics, the way people react to perceived job characteristics, and the way people feel at work (Schaufeli and Taris, 2014). Moreover, job characteristics can also impact personal resources, thus rendering a dynamic role for personal resources in the JD-R model.

The challenge and hindrance stressor framework has also recently been integrated into the JD-R model to provide a finer-grained account of different types of job stressors (Cavanaugh et al., 2000; Crawford et al., 2010). Challenge job demands, although appraised as stressful demands, tend to promote goal achievement, learning, and growth because they are perceived as generally nonthreatening hurdles to overcome in pursuit of valued outcomes. High workload, for instance, would be a challenge job demand because it is stressful but usually associated with desired outcomes of recognition and reward once the necessary tasks are accomplished. Hindrance job demands, on the other hand, impede goal achievement, learning, and growth (Crawford et al., 2010). For example, administrative paperwork could be viewed as a hindrance job demand because fulfilling the demand usually gets in the way of achieving work goals. Challenge job demands can be both motivating and exhausting since individuals have to deploy their resources to meet the challenge. Hindrance job demands, on the other hand, are associated with lower levels of motivation and higher levels of strain.

The heuristics nature of the JD-R model adds to its flexibility to different kinds of occupational contexts, which, on the other hand, limits its generalizability such that research finding concerning a specific job demand might not apply to *all* demands (Schaufeli and Taris, 2014). Moreover, the model only specifies two psychological processes through which job characteristics influence job strain, leading many researchers to incorporate other stress models to provide a fine-grained examination. With its limitations being said, the JD-R model is still one of the most influential theoretical frameworks for job stress research. Empirical evidence provides strong support for the basic contention and the two processes of the model. As is evidenced by the current review, the JD-R model has also generated more refined inquiries into specific components of the model such as the role of personal resources and important distinction between challenge stressors and hindrance stressors. The JD-R model will continue to stimulate more scientific endeavor to better understand workplace stressors (Schaufeli and Taris, 2014).

Workplace Stress Interventions

Significantly more empirical attention has been paid to identifying the negative effects of stressors than has been paid to reducing either the incidence, or the effects, of these stressors. Nonetheless, over the past 20 years, a good deal of evidence has accumulated that indicates the relative effectiveness of a variety of programs in reducing workplace stress, with some of these interventions guided by theoretical models. We will briefly discuss such programs, highlighting primary, secondary, and tertiary intervention strategies.

Primary Interventions

Primary interventions focus on prevention or elimination of stressors in the workplace through the utilization of work redesign and organizational change and development. For instance, if poor management appears to be causing strain within individuals at work, then a primary intervention could involve management restructuring. Alternately, if a job involves a good deal of physical work resulting in lower back pain (e.g., nursing), lift-assisting machines could potentially be added to reduce this stressor (therefore reducing the strain). By Tatrgeting the source of workplace stress, these primary interventions can, in theory, also eliminate the strains that result from the stressors.

Empirical research on primary intervention is relatively sparse, as changing the workplace can be costly and is not always practical or possible. However, a careful search of the literature does yield a small, but informative, group of studies that demonstrate the effectiveness of primary intervention strategies. For instance, primary interventions involving changes to the work environment, redesigning individual jobs, and training have been linked to decreased levels of employee depression and resulting absenteeism (Kawakami et al., 1997). The evidence is even more abundant that primary interventions

focused on work redesign can reduce physical strain – particularly back pain – associated with heavy lifting in the workplace (Tveito et al., 2004).

Organizations have also begun to focus on increasing autonomy or participation in the workplace as potential primary inventions. As per the JDC and JD-R models of stress, increasing autonomy and participation could work to both reduce stressors and their associated costs. Such interventions typically involve increasing decision latitude and skill discretion of individual employees without adding duties. That is, employees maintain the same tasks in their job description, but are allowed more discretion in determining how to complete the tasks. These interventions have been shown to have beneficial effects on employees, particularly when autonomy and participatory behavior are combined with environmental changes (e.g., Bond and Bunce, 2001).

Despite evidence that primary interventions can be effective, efforts such as work redesign and increasing employee autonomy and participation are not always possible or desirable from the viewpoint of management. For instance, for jobs with inherently high levels of job demands (executives, police officers, and firefighters), only so much can be done to redesign the job. Many of the major stressors in these positions are simply unavoidable. As such, the majority of research has investigated interventions designed to mitigate the effects of stressors either through stress management tactics (secondary interventions) or through healing the negative effects of stressors (tertiary interventions).

Secondary Interventions

Secondary interventions focus on teaching employees to manage stressors at work, emphasizing and teaching the use of effective coping strategies. That is, they involve teaching employees what to do when faced with a stressor. Secondary interventions most often manifest as stress management programs which can vary widely in terms of content, from time management to progressive muscle relaxation and meditation. Because of this variety, and because individual differences play an important role in individual level stress management techniques, it is difficult to make a unilateral judgment about the effectiveness of secondary interventions. However, a good deal of evidence has accumulated for individual aspects of stress management programs. For instance, significant evidence supports the benefits of meditation and relaxation training in reducing strain associated with stressor exposure. Alternately, training programs that have focused on adaptive coping strategies – time management, organization, and problem-focused coping – have shown mixed results (e.g., Macan, 1996), though it is important to note that there is little systematic research investigating the effectiveness of these types of stress management programs.

Finally, health promotion programs – a particular type of stress management program that promotes healthy living through diet, exercise, and other processes (sleep habits) – are designed to promote resiliency in employees through increasing well-being and vitality so that stressors are less likely to lead to negative outcomes. Health promotion approaches have been shown to be relatively effective in reducing strains associated with work stressors. The research in this area also indicates that the benefits of health promotion programs might cross to nonwork domains, benefiting general life satisfaction, and personal relationships. For an excellent meta-analysis investigating the outcomes of different types of stress management programs, see Richardson and Rothstein (2008).

Tertiary Interventions

Whereas secondary interventions focus on helping individuals to identify, manage, and cope with their stressors, thereby reducing the negative effects, tertiary interventions focus on healing the negative effects after they have already occurred. The most common tertiary interventions provided by organizations are employee assistance programs (EAPs). These programs (now primarily externalized by contracted EAP vendors) typically offer a range of services, including counseling and referral services, where an employee can receive a limited number of mental health services free of cost (to the employee). Oftentimes, the benefits provided by an EAP extend to the immediate family of an employee, as well.

As with stress management programs, it is difficult to evaluate the effectiveness of EAPs, given that the programs differ greatly in the quality of the services, as well as the manner in which services are provided. Additionally, many of the available studies rely on single organization samples (i.e., case studies), and are reported by the providers of the EAPs, which might indicate bias. Furthermore, the largest group of studies that investigate EAPs focus on return-on-investment for organizations as opposed to employee outcomes. The results of empirical studies that actually investigate the effects of EAPs on employee strain are mixed, with some showing that EAPs have no positive effect on health or absenteeism and others have finding increased job satisfaction and lowered health care costs (implying a healthier workforce). Overall, these inconsistent results point to the importance of more systematic research on the effects of EAPs, with an emphasis on determining moderators that might contribute to these varied findings.

Contemporary Issues in Workplace Stress Research

Measurement Issues and Advances

Historically, workplace stress literature has been relatively limited by methodological concerns. Namely, the majority of this research has been self-report and cross sectional in nature, particularly before the twenty-first century. This, of course, severely limits the conclusions that can be drawn about the relationship between stressors and strains, where reverse causality (strains leading to stressors) is a possible explanation for findings, and where common method concerns are exacerbated. For instance, in a cross-sectional study linking interpersonal conflict and burnout, stress theories (e.g., JD-R) would suggest that the conflict *results* in burnout, but, due to the cross-sectional nature of the data, it may be that more burnt-out people are more likely to initiate conflict with others.

However, there have recently been strides in the methodology of workplace stress research. Specifically, the long-ignored call for more longitudinal studies on the stressor–strain

relationship has been recently heeded, and much of the stress literature now published involves two or more time points of data collection. This allows researchers to demonstrate temporal contiguity – that the stressors precede the strains. The time lag between waves of data collection can provide insights into both the short- and long-term implications of stressors. For instance, a study that examined the stressor–strain relationship across several years can provide insight into potential negative effects associated with prolonged exposure to stressors. Shorter term studies, however, can provide insight into the immediate reactions to stressors, and provide a more microview of the phenomenon.

Along those lines, diary studies have become more popular (though still relatively infrequent) in workplace stress research. Diary studies allow researchers to survey people multiple times within a relatively short period of time. For instance, employees could respond to measures once per day for a month. Assessments are typically conducted through communication technology (CT), such as e-mails, smart phones, or tablets (which may be provided by the researchers). A similar method – experience sampling – assesses people multiple times within a single day. Both of these methods have provided more insight to the daily, within-person impact of stressors. These methods have been particularly effective in understanding how mood can impact the perception of stressors, and how emotions can mediate the stressor–strain relationship (see Harris et al., 2003, as an example).

There has also been a push to understand how work stress might be more than just an individual level phenomenon. That is, given that people at work are often nested within a work group, within a department, within an organization, it is likely that the experience of stress is not independent of these levels. Based on this literature, group-level variables (such as workplace climate or group efficacy) could potentially have a direct effect on individual and group reports of strain, and may also moderate the stressor–strain relationship. The immediate benefit of multilevel research is that these studies provide additional perspectives and guidance to organizations seeking to develop interventions. As mentioned earlier, most interventions tend to be focused on the individual (e.g., relaxation training, EAPs), but results from multilevel studies could potentially inform effective, group-level interventions, though little research has been conducted in this area.

In terms of assessment of stressors and strains, researchers are more frequently moving away from self-report and using coworker or supervisor reports of stressors to gain perspective on how stressors are largely the result of perception. That is, an employee might perceive their workload as high while a supervisor reports that same workload as relatively light, which offers some insight into individual differences in perception. Additionally, some workplace research actually utilizes physiological measures of strain, such as cortisol levels, blood pressure, heart rate, and diagnosed disease conditions. These more objective measures of strain allow researchers to better understand how stressors affect the body, and allow more concise and accurate validation of self-report strain measures. Typically, such studies find small, but significant relations between self-reported stressors and physiological measures.

Finally, the pursuit of different methodologies for assessing and understanding workplace stress has led to more sophisticated statistical analyses. Early stress research was marked by relatively simple tests of the stressor–strain relationship. Recently, there has been a push to incorporate analyses such as Structural Equation Modeling, Hierarchical Linear Modeling, and Latent Growth Modeling to answer more sophisticated questions about the relationships among stressors and strains, as well as antecedents, mediators, and moderators of these relationships. Overall, this push for more methodological and statistical sophistication has led to a more informed body of literature in the workplace stress area, primarily though allowing contemporary models (JD-R; ERI) to be tested more dynamically.

Contemporary Topics in Workplace Stress

With the way that the workplace has continued to change across the past 20 years, researchers are beginning to pay attention to a variety of new (or sometimes ignored) workplace stress issues. One relatively new topic is the computerization of the workforce and the impact of CT (e-mail, text messages), especially the persistent use of smart phones. More employees work in front of computers than ever before, and researchers are beginning to investigate the impact of this computer use, both in terms of the physical and the psychological impact. Particularly, new research is beginning to investigate the impact of 'cyber incivility' and 'cyber bullying', where people accidentally, or intentionally, mistreat each other using computer-mediated communication (e.g., e-mails, text messages; Lim and Teo, 2009). This preliminary research has shown that cyber incivility can have a strong, negative impact on employee strain, perhaps even stronger than face-to-face incivility. However, this area is still new, and there are many questions that have yet to be answered.

Along those lines, the persistent use of CT is beginning to spark interest in the work-life conflict literature. That is, the boundaries between the work and nonwork domains are becoming more permeable, leading to more work-life conflict. The research is quite new in this area, and researchers are actively attempting to determine which employees – in terms of individual difference and preferences – tend thrive or stagnate in occupations with these blurred boundaries. More generally speaking, a great deal of attention has been paid to the impact of work-life balance on employee strain outcomes in the past 10 years, and we expect this literature to continue to grow. More people than ever are in the workforce – particularly women – and approximately 5% of the population work multiple jobs (with this number growing). This indicates that, for many employees, work-life conflict may be increasing, and researchers are working to determine factors to lessen, or at least alter perceptions of, this conflict.

In addition to technology-related and work-life stressors, the diversification and globalization of the workforce has led to concerns about stressors and strains experienced by different groups. Specifically, there is a growing body of literature examining how women and underrepresented minorities (i.e., racioethnic and sexual orientation status) might experience a disproportionate number of stressors in the workplace. Particularly, these stressors tend to be interpersonal in nature,

where these groups experience higher levels of outright harassment, as well as more 'modern' forms of subtle discrimination such as incivility. These stressors have been shown to relate to strain in these groups, and people who share multiple minority statuses (e.g., minority females) may experience worse strain as a result of compounding forms of harassment (Raver and Nishii, 2010). As such, researchers have been investigating methods for reducing harmful stressors for at-risk populations. Climate-based interventions may be effective, such that organizations that strive to create a climate for civility, climate for women, and climate for diversity seem to have lower levels of harassment of these at-risk groups. However, research in this area is still primarily associative, and certainly merits further investigation.

A final burgeoning topic in the workplace stress literature is eustress, or so-called good stress. The most commonly used definition of eustress in the workplace literature is that eustress represents a positive perception of stressors (whereas 'distress' represents a negative perception). This perception may be influenced by a variety of factors, including individual differences and characteristics of the stressor (e.g., timing, whether it is self-imposed or external, etc.). The concept of eustress has received limited empirical attention in the research, and may be most clearly lacking in the organizational literature, though some research seems to indicate benefits from eustress. Particularly, research on the challenge-hindrance distinction of stressors seems to indicate that challenges may be indicative of eustress, which could potentially reduce strain outcomes (Van den Broeck et al., 2010). Similarly, research in demanding occupations, such as health care workers, indicate that some nurses react to stressors with feelings of energy, hope, and gratitude (Simmons and Nelson, 2001). The factors that predict eustress are still unclear, and are a clear direction for future research.

Future Directions and Conclusions

Though workplace stress research has certainly made strides across the past 20 years, it is far from complete. First, in terms of contemporary theories of workplace stress, researchers need to continue testing, and refining, these models. For instance, the JD-R model was designed to be a *descriptive, heuristic* model, which posits that demands and resources, in general, impact workplace outcomes. The model is broad and generalizable, but does not specify psychological processes that link demands and resources to strain outcomes. For a summary of the JD-R model, including its limitations and calls for future research, see Schaufeli and Taris (2014). In terms of COR theory, the field is moving away from discussing personal resources in general, and toward assessing specific resources, and how they might impact the stressor–strain relationship. Indeed, these resources could potentially be incorporated into the JD-R model, combining COR and JD-R theories, and researchers are beginning to discuss this possibility. In fact, the incorporation of multiple workplace stress theories in a single study can allow for greater theoretical precision, and result in better overall understanding of observed and predicted relationships. Researchers should also continue investigating how changing technology, including CT, can impact individual outcomes. Along these lines, this technology may have a differential impact on employees based various demographic factors. One such factor may be age, as some research has demonstrated that older workers are less skilled with technology and require more time and training to learn new technologies. Given that the workforce is rapidly aging in many countries, it is important to understand the implications of technology use on this group. More generally, topics related to workplace stress and aging should continue to be investigated.

Finally, given that diversity and inclusion-related issues are an increasingly important topic in workplace stress literature, there is a need to continue identifying stressors faced by at-risk groups, especially subtle stressors. It is also important to explicitly investigate interventions that might be effective in eliminating these stressors, with a particular emphasis on climate-related interventions. Finally, researchers are beginning to incorporate positive psychology topics, such as eustress, into the workplace stress research. These topics certainly merit investigation, particularly for identifying what types of people may thrive under stress. Positive psychology is perhaps dually beneficial, as aspects can be incorporated into the study of any of the other stress-related topics discussed.

To conclude, workplace stress research has gained significant momentum over the past two decades, and clear strides have been made in developing theories, conducting empirical research, and creating interventions. However, our understanding of workplace stress is still far from complete, and we urge researchers to continue investigating the important areas that we highlighted for research, as well as other important topical areas.

World Republic

Abstract

The article starts from the diagnosis of globalization. If its implications are taken seriously, it is argued, the establishment of a world legal order and eventually of a world republic is demanded from a moral point of view. In discussing eight possible objections to the concept of a world republic, the concept's more detailed characteristics and implications emerge clearer into focus.

Our age of globalization asks for the establishment of a world legal order, ultimately even for a world state or a world republic, since 'world republic' means a legal and social community which extends over the whole world. If one compares the world republic to a ship, one might think of Antoine de Saint-Exupéry's saying: "créer le navire c'est exclusivement fonder le pente vers la mer," ("building a ship simply means to create the longing for the sea": 1959: p. 826). Political scientists examine the lumber for the ship. Their naive counterpart, an idealistic utopia, on the one hand, offers suggestions of how one might travel the sea without any lumber at all. Philosophy, on the other hand, develops concepts for a feasible 'not yet': it sketches a realistic vision of how one might carry over the common heritage of humanity, the right, and, furthermore, the political achievement of the modern era, liberal democracy, to the age of globalization. Since who has reasonable hopes, does not shrink from possible difficulties.

The most important philosopher who advocates a world republic is Immanuel Kant in his *Perpetual Peace*. Communitarianism is a modern objector to the idea of a world republic, arguing that a world republic would threaten the political and social integrity of the single states. Cosmopolitans such as Charles Beitz (1979), however, consider the single nation-states as a historical steppingstone, and advocate a homogenous world republic that eventually will incorporate and thus dissolve the single states.

An apt justification starts out with a diagnosis of globalization (1), since everybody talks about globalization today; what the term actually refers to, anyway, often remains unclear. It follows – as a therapy – the world republic (2), which needs to be defended against some misconceptions. Finally, we will come through the discussion of eight objections (3), to the following insight: "Créer un ordre juridique mondiale, c'est avant tout fonder la pente vers la paix et la justice globale" ("To establish a world legal order means, first and foremost, to create the longing for global peace and global justice").

Diagnosis: Globalization

Strangely, it is still common to picture globalization in a reductionist economic perspective; one only thinks about economic and financial markets, at most also about labor markets, tourism, and environmental protection. The truth is, however, that the sciences, the school and university system, and all facets of culture globalize as well. One should not forget that long before the first computer was built the writings of Plato, Aristotle, and Kant were distributed over the world, also the works of Homer, Dante, Shakespeare, and Goethe, the tales from *One Thousand and One Nights* and texts of eastern wisdom. Likewise, all around the world people listen to Bach, Beethoven, and Mozart, Jazz, and certain pop music. All around the world people admire Indian temples, Japanese Zen-gardens, and European castles and churches. All around the world people study quantum theory, mathematical analysis, and the building blocks of life. And long before all these various products of arts and sciences, various religions have spread all over the world.

Against the reductionist economic perspective one might also point to the noneconomic causes of the economic globalization: political decisions and technical innovations. Even the economic globalization itself is not something completely new. Already at school we have heard about international trade routes like the Silk Road, the emerging world trade zone with world market prices and world trading centers like Alexandria in Hellenistic times, and a dense trade system in the times of gold currency.

New are, however, elements that are based on innovations like broadcast satellites and the Internet: that information can be exchanged within seconds and events can be perceived almost simultaneously worldwide. The Internet also bears a huge democratic potential. It does not entail equal distribution of usage, but nevertheless treats all persons, enterprises, and states equally. Furthermore, its information bypasses the censorship of autocratic states, exerts pressure for democratization, and facilitates worldwide protest against violations of human rights. Moreover, there is an economic benefit: a person who travels the Internet reduces his or her environmental footprint and increases his or her legal security, because at least his or her life and limb are not at risk.

The Internet, however, is also of use for global terrorism and organized crime. Since there are also innovations in the sector of military technology, the first dimension of globalization, the multifaceted 'community of cooperation,' couples with a second dimension which is, unfortunately, again rich of facets, the 'global community of violence.' And in the burdens that follow from international competition, we recognize the third dimension, the global community of solidarity, the worldwide 'community of misery and suffering.' By now the large movements of refugees and the high amount of other

migratory movements make it apparent that neither the consequences of civil wars nor of economic as well as legal and political underdevelopment stop at national borders.

Therapy: World Republic

Since all three dimensions demand for global action, this observation is linked to the question of how to respond. Let us approach this question topically and draw on some widespread assumptions.

Humanity knows two basic models of visionary power for laying out the structure of communal life, liberal democracy, and a contest of powers. The first model says that (1) we should use law instead of violence; (2) law should be based on human rights; which in turn demands that the (3) establishment of public institutions (4) by the people who are governed by these institutions. Moreover, (5) it is called for commitment in civic society. These five elements – law, human rights, statehood, more democracy, and civic society – are categorical and universal. They are elements of a morality of law. Our human desire for right and justice is combined with the call of a duty of the morality of right.

A liberal democracy consisting of these five elements of course considers a strong 'statism,' which tries to solve all tasks by coercive intervention, to be foolish. Instead, such a democracy leaves room for the free play of powers, competition in economic, but also political, academic, and cultural spheres. Because of the creativity, efforts, and willingness to take on risks that is released in the market, one expects an age-old dream of humanity to become true. According to the prophetic word, "their swords will be turned into plough-blades, and their spears into vine-knives" (Jesaja 2,4), military force shall be turned into economic and cultural power and there shall be peace combined with scientific development and economic and cultural prosperity.

Because of their universal scope the five elements mentioned not only bind particular political communities, but also the international relations. Hence, the idea of a worldwide peace and legal order emerges in which societies and in particular individuals prosper through economic, academic, and cultural competition.

Political philosophy acknowledges also the second vision, the wealth promising competition. Political philosophy, however, rejects its absolutization, the neoliberal replacement of politics by markets. There is a lot that the world society might leave to free competition and contingent evolution. Anyway, the framework of this competition needs to set likewise in a particular state and the world society. It is called for a world legal order, that is bound to human rights and democracy – not only but also because interstate violence, the wildfire that flares up every once in a while, can only be erased that way. The price for globalization shall not be paid with a regression in liberal democracy.

One might ask: 'Why not?' The response is evident, however. As far as the pragmatic reason, the promised multifaceted wealth, speaks in favor of globalization liberal democracy is, because of its being an element of the morality of right, of higher value and cannot be sacrificed to wealth which is a lower ranked value. As far as globalization is legitimated functionally by promoting freedom and democracy – in other words, if globalization is supposed to serve democracy – it would be irrational to sacrifice democracy for democracy. Perhaps such a proceeding is dishonest: one talks about democracy and actually means one's own power, either like some neoliberal economists the supremacy of economic and financial markets or like politicians of the contemporary hegemonic power the supremacy of their own country.

If one gives priority, on the contrary, to liberal democracy, the spreading of its basic elements over the global sphere is inevitable. In the same way that a particular society coerces the economic and cultural market forces to follow the framework of human rights and democracy, global demands for action call for a global legal order of a democratic layout, that is to say a liberal world democracy, including a global civic society, in a nutshell: a world republic. (For a detailed design of the world republic and a profound substantiation: (Höffe, 1999/2007); for a discussion of this approach: (Gosepath and Merle, 2002); cf as well Lutz-Bachmann and Bohrman, 2002.)

Eight Objections

Though the global call for action in combination with law and democracy urges the establishment of a world republic, such a world republic breaks with familiar ideas. As a consequence, skepticism spreads. We can counter this skepticism with a new method: a modest form of Hegel's determinate negation. By way of the discussion of eight objections the vision world republic reveals her modest, hence, realistic profile.

Priority of Statehood?

According to a first objection, statehood is given a priority over its alternatives – market, 'governance without government,' and a network of global civic constitutions – that are denied the power and capability to coordinate.

The response to this objection is based on a modest understanding of statehood: for the very reason that what law means, that is the impartial enforcement of common rules, does not remain a pious hope, the enforcement should neither be entrusted to one of the parties affected nor to contingent evolution. On the contrary, nonprivate, that is to say public powers, have to take on responsibility without privileging the existing structure of public power. Statehood means nothing more and nothing less than the notion of a nonprivate responsibility. A responsibility for shaping legal norms, for enforcing them, and to settle disputes. Moreover, I do not picture global statehood as statist, but as state centered. Since the global civic society, the cosmopolitan society is a part of the world republic, nongovernmental organizations need to be given possibilities for cogoverning in certain limits.

Two Models

According to the second objection, the vision of a world republic asks too much of humanity. Though there have been tendencies toward globalization for a long time, humanity never established a global order. Why should we be able to do what mankind has not achieved in the past?

The response to this question is twofold. On the one hand, the global call for action increased enormously. To fight environmental damage, terrorism, and organized crime, as well as poverty, underdevelopment, and oppression global agreements are indispensable – in any case much more important than the spread of philosophy and science.

On the other hand, there are at the minimum two examples of a successful supranational law. Against the danger of cultural bias, the two examples are taken from two very different legal cultures. The first example stems from outside of the Western culture.

It is the Iroquois Peace Coalition and League of Nations that was founded presumably in the sixteenth century (see Morgan, 1851; Tooker, 1978). The second example is an ancient European model, the *ius gentium*, developed in the Roman Empire, which in that time was a highly complex multicultural community.

The idea of a worldwide, cosmopolitan order is at least as old as the cynic Diogenes of Sinope. When he, driven from his homeland, calls himself a 'citizen of the world' (cf Diogenes Laertius, VI 63), he has no legal institutions in mind. The same is true with the second founder of the Stoa, Chrysippus; his cosmopolis does not yet appear as the legally ordered community, but as an open space of action, not qualified further (*Stoicorum veterum fragmenta* II 32; 328). The Roman *ius gentium*, on the other hand is actually law – and this is our first factor. The same applies to the peace coalitions of the Iroquois. The desire for peaceful coexistence might be as old as humanity itself. Only in a ceremonially sealed coalition, however, does it maintain its legal bindingness.

This does not originate from fulfilled wishes, but – secondly – from an urgent call for action. The Iroquois had been tired of war, and in Rome, one had to regulate the increasing trade traffic between citizens of various communities and cultures. Therefore, the new law is subsidiary in the original sense: it helps in an emergency, namely, whenever the previously competent institutions no longer suffice. Also, it does not extend 'imperialistically' to all legal areas, but acts with a wiser modesty. The Iroquois limit themselves to the international domain, as their alliance belongs to an international law. In Rome it has to do with the then-urgent call for action regarding business and trade law, while constitutional law and administrative policy, as well as religious law and case law are excluded (cf Kaser, 1993). The Roman *ius gentium* is primarily an international commercial law, an *ius gentium commerciale*.

Because the other legal domains remain untouched, the new law seeks a completion of what is already known, not its replacement. It is, thirdly, complementary. Rome might have been able to exercise its hegemonic power more freely, though perhaps at the price of loosing a good portion of its trade traffic. Whether out of legal and moral, or, more probably, out of pragmatic reasons, a once again modest Rome returns, fourthly, to a consensus, even to a double one, that is, to a 'theoretical' and to a lived, 'practical' consensus. Instead of imposing a law upon others, one appeals, on the one hand, to the agreement of all cultures that is indicated in the expression *gentium*: it makes use of an interculturally valid ground of obligation. For example, the obligations (including sales, rent, management, etc.) are grounded upon the requirement to keep one's word, the *fides* that bind all human beings equally, independently of their ethnic and religious affiliation, as well as of their citizenship. On the other hand, one seizes the trade and traffic requirements that were customary in Rome's international market. Because there was no apparent hegemonic power among the Iroquois, they proceeded consensually as well.

The fifth factor is already implicit in the fourth factor. It lies in the renunciation of particularities, in the indifferent vis-à-vis difference: the Iroquois oppose their differences, while Rome is as good as indifferent to all cultural differences.

One characteristic of Rome deserves its own mention. The Roman *ius civile* contains religious formal requirements to which the concerned citizenry is bound, but which are unnecessarily complicated. The *ius gentium*, however, separates itself from religious obligations. It features, sixthly, a secularization (though this is missing with the Iroquois) that is not only connected with simplification, but also, seventhly, with a concentration on the heart of the legal transaction: on the wills of the parties concerned.

The parties concerned count as equal: this is the eighth success factor. Whether rich or poor, whether Egyptian, Roman, or Jew, whether pious or irreligious, the *ius gentium* treats everyone equally, though, of course, it does not yet cover every legal domain. The legal equality primarily reigns in contract law, though not in family law or law of inheritance. While princes still rule in Europe 'by the grace of God,' the Iroquois, long before the first declaration of human rights, the *Virginia Bill of Rights*, add, 'Equal, without the superiority of the chiefs.'

Because all of these factors come together – aside from (1) the character of law, there is also (2) subsidiarity and (3) complementarity, (4) the search for both a theoretical and a practical consensus, (5) neutrality toward cultural particularities, (6) secularization, (7) concentration on the legal transaction itself, and (8) the (extensive) equal rights of all concerned – the *ius gentium* is the model for the world in the sense that it is compatible with the world, that is, capable of governing in an agreeable way the coexistence of cultures from the entire world.

A further, ninth factor opposes 'globalist' parochialism. Notably, it is not an international law, but a Roman authority that supports the *ius gentium* jurisdiction of the foreign praetor. This reveals itself as an apparently paradoxical law, a world law that can neither establish a world organization nor can be established by it: a national world law.

Hence, the second objection can be answered not only by reference to the increased necessity for action but also by facts on the ground.

Ungovernability?

A third objection is: the world republic is such a giant project that it will remain ungovernable because of its size and complexity. The answer to this objection increases the modesty in the idea of a world republic.

For Liechtenstein (with its 28.500 inhabitants), Switzerland (with eight million inhabitants) is a giant and the United States (with 340 millions inhabitants) a monstrosity. If, however, a society like the United States can be governed, though it is 10 000 times as big as Liechtenstein and still 40 times as big as Switzerland, the third objection cannot be a knockdown

argument. We cannot regard the third objection as an absolute veto, but only as a relative veto, nevertheless as a constructive one: the vision of a world republic remains permissible, even necessary – under the premise that it is able to prevent ungovernability as well as overcompensation, excessive bureaucratization, or a police state. For this overcompensation is the vision that frightens most people, not a liberal world republic.

For spelling out how the detailed set up of the world republic is to be like, political imagination and experience are needed. Both already suggest two things. On the one hand, the world republic should not be understood in too statist terms, since a global civic society is one of its essential building blocks. On the other hand, it seems to be recommended to slide in political units of continental and subcontinental size. Following the model of the European Union, most problems could be solved 'at home' and only problems that call for global action would need to be handed over to the global order. These problems, however, range from fighting terrorism and organized crime – when it crosses the borders of the smaller unions – over the establishment of a global peace order that guarantees peace within and between the unions, and social and ecological minimum criteria, perhaps also a world competition regulatory body and a global supervision of banks, to the establishment of world courts, like the International Criminal Court. The response to the third objection is anyway: world civic society plus larger regional intermediate units.

A Threat to Human Rights?

According to a fourth objection, a world state puts at risk the great achievements of civilization, namely, human rights and civil rights. For up to now, only the individual state has succeeded in guaranteeing such rights. This argument is correct not only in its underlying normative prerequisite – the obligation of every state to uphold human rights and civil rights – but also in its empirical assertion. However, only one-third of this claim is true.

Without a doubt, in the Western world, it is predominantly states that protect human rights and civil rights (although in the case of Europe the analysis needs to be qualified so as to include the European Convention on Human Rights, the European Court of Human Rights, and the European Commission on Human Rights). All citizens who obtain such protection only from international organizations tend to fare embarrassingly badly. However, the second third of the truth reminds us that Western states themselves have actually threatened these rights at some point in the past: France pursued the Huguenots; the United States is founded by religious refugees who escaped the intolerance prevailing in Great Britain at the time, and the United States itself permitted slavery well into the middle nineteenth century. The last third of the truth consists of the principle of subsidiarity: where human rights and civil rights are already protected – either state-internally or through human rights conventions established by larger regional units – the world republic can and should stay in the background. Yet, in case of massive human rights violations or genocide, such restraints are only warranted if the ('humanitarian') intervention creates even more evil than before; a general restraint, however, is not justifiable (see Höffe, 1999/2007: ch. 14.3).

Hence, the fourth objection, once more, does not have the force of an absolute veto, but only that of a constructive veto. It confirms the principles of federalism and subsidiarity: the primary protection of the law remains the responsibility of the individual states, which is why they deserve the rank of primary states. Such status entails an original (not derived) authority to legislate as well as an original responsibility for the finances. The world republic is only a complementary state, a secondary state, and, in cases where a regional intermediate level is introduced also, more modestly still a tertiary state. At any rate, the world republic does not constitute a single, unitary state that extends across the entire globe, but a state of states: a state of multiple nations.

According to the principle of global subsidiarity, the world republic is not legitimized from above, but democratically through the citizens and individual states. Yet, it assumes only those remaining responsibilities that the primary republics and larger regional units alone cannot master at all or not nearly as well. In the first case, the world republic has a compulsory responsibility; in the second case, it has an optional responsibility. Added to that, the 'principle of care and circumspection' applies: they must not endanger the degree of qualified democracy that individual states and larger regions have already attained.

States as well as larger regional unions that are committed to liberal democracy possess legitimacy, which implies no obligation to dissolve. In some places, one likes to declare the nation state as outdated. The truth is, however, that despite its perversions it became the worldwide dominant model because of its important accomplishments. For instance, religious and economic freedoms of individuals follow from its separation of state and society. Economy and the material wealth created by it as well as modern administration is, in turn, hardly conceivable without the extent of social integration that we find in nation-states. The renewal of the European education and science, the increase of the educational level of all citizens, and the establishment of a welfare state are also accomplishments rooted in the nation-state. Furthermore, the state admits the thought of basic and human rights, advances the sovereignty of the people and establishes a parliament. Moreover, it abolishes serfdom, feudal privileges, and the legal inequality of women. Finally, the supplement, the civic society grows – sometimes in opposition to the established governmental institutions – first and foremost within states and still helps these to fulfill many tasks and be at the same time more citizen-oriented and efficient.

For reasons like that philosophy gives the world republic a subsidiary and complementary rank. And because of the so-defined rank of the world republic, philosophy is not dreaming a sweet dream that modifies the reality of the world according to its needs. The world republic does not promise, anyway, the all-encompassing well-being which religions call 'salvation' and rightly do not expect for this world. The world republic that is called for is an ideal, and humanity is morally obliged to realize it. Fortunately, humanity already brought its establishment on its way to: the mere coexistence of states and their working against each other has been replaced by a dense net of economic, academic, and cultural, even political, and sometimes even ecological cooperation.

To a large part, all this still amounts to a political 'too little,' because an executive power is missing. And the singular, the single ultraminimal state, has given way to a plural: a regional as well as thematically ('sectoral defined legal regimes') complex multiplicity. Moreover, a common state power is not emerging yet. It might even remain an open question whether the world republic needs the establishment of a unified head and a monolithic center. A part of the agreements mentioned starts to take over legislative tasks by means of binding statements in such a way that one might speak of the beginnings of and the equivalents to legislation, a 'soft legislation.' In cases where international inspections and sanctions are planned, executive power emerges, a 'soft executive power,' which carries the cutback of national sovereign rights further forward. It is extended, in cases where additional international arbitral authorities or even courts of justice, a 'soft jurisdiction,' are established. If we take all these elements together, we already see the first beginnings of a 'soft world republic.'

Global Peace by Means of Global Democratization?

According to the fifth objection, there is a more simple way of achieving the protection of human rights: democratization of all states. In line with the thesis 'global peace by means of global democratization' one could be content with a global democratization policy. The world republic would be dispensable, according to this reasoning.

Undeniably, liberal democracy protects human rights already domestically. It seems to be appropriate, however, that a global human rights commission is established that checks this protection like the European Commission of Human Rights especially in cases where the protection of human rights did not already become natural because of a long practice of human rights standards. Most notably, the states themselves need protection: of their territorial integrity and their political and cultural self-determination.

On the danger of a war of aggression political science did take on Kant's famous thesis: republics, meaning pretty much liberal democracies, do not tend to engage in wars of aggression (*Perpetual Peace*, 1. Definitive Article, VIII 351). History, however, gives us reason for being skeptical: the young French Republic inflicted war on Europe and pursued a clear interest to rule. The United States expanded to the West without taking the rights of the native inhabitants into account. Furthermore, they annexed Texas and incorporated Arizona, Nevada, Utah, California, and New Mexico after their war with Mexico. Nor did Great Britain's development toward a republic hinder it from having plans to become a world power, the expansion of the Commonwealth.

One of the reasons for this is that Kant's argument, the well-considered self-interest, is correct, but has not the wished momentousness, since it is not *always* an argument against war. Wars that happen far away are not as important to the citizens and wars against apparently weaker enemies are even less important to them. Furthermore, wars may distract the public from domestic problems. Moreover, there is money in wars. Finally, there are legal problems below the war threshold. Consequently, the fifth objection has again only the power of a constructive veto: the legal protection and the protection of peace that is already brought about by the worldwide democratization remains in its hands. However, states also have a claim to a legal solution of conflicts like individuals as opposed to a solution by power. Hence, a worldwide legal order with public powers is called for.

Deficit in a Global Common Sense of Justice?

According to the sixth objection, a world legal order presupposes something that is in fact missing: a globally common sense of justice.

It is apparent that even the West is lacking a common sense of justice. The amount that is paid for indemnity in civil lawsuits, for instance, is much higher in the United States than in Europe and there are significant differences concerning the question what is to be admissible as evidence in criminal trials. Even stronger differences become evident in the attitudes toward death penalty, corporal punishment, and the treatment of dissidents. However, besides these apparent differences, there are in fact substantial similarities: equality and impartiality are globally recognized as essential in the application of law. The same is true of procedural rules like 'one shall listen to the other party as well' or the presumption of innocence. Furthermore, the same basic goods are legally protected by almost all legal orders: life and limb, property and honor. Moreover, it is neither allowed to manipulate weights and measures nor to falsify documents. Additionally, the environment is protected, for instance, by the prohibition of poisoning wells and the institution of protective forests. On top of that, the human rights treaties of the United Nations prove many more similarities. It is 'only' lacking the commitment to enforce these similarities impartially and effectively. The constructive veto in this case is, therefore, almost mundane: the global sense of justice needs some more time to be given complete expression. The existing similarities, anyway, are already big enough to make the establishment of world courts possible: the International Court of Justice, the International Tribunal for the Law of the Sea, and the International Criminal Court – despite the veto of the United States.

The world courts, again, are governed by the principle of subsidiarity. They do not replace the national jurisdiction. They simply extend it to a new level, via the jurisdiction of a greater region like the European Court of Justice to a global jurisdiction. Apart from that the 'national' level needs to change also and it is called for the establishment of a 'national world criminal law,' which is completely compatible with human rights standards.

Global Public

An indispensable institution of a functioning community is a political public (see Höffe, 1999/2007: ch. 4.3), a requirement that gives rise to problems that are well known at the level of large-scale regional unions such as the European Union. These difficulties are exacerbated even further in the case of a world state, a fact that allows us to forward another, seventh, objection: a world state without a world public, a global public, is unreasonable.

Fortunately, attempts toward a global political public can already be attested. They are found, for instance, in the media reports on violations of rights all over the world, which induces

reactions by the 'general public' virtually everywhere. Kant was able to state for his own time that "a violation of rights in one place is felt throughout the world" (Perpetual Peace, 3rd definitive article: VIII 60). Yet, he pays attention neither to the danger of a selective, biased perception of rights violations, nor to the fact that opposing voices can also be heard: collective prejudices, national superciliousness and even appeals to break the law and violate peace. Moreover, an effective global public has far more tasks to perform than merely function as a medium for the outrage of rights violations.

According to three stages of the principle of the 'public,' global politics is, firstly, to happen in a public manner so that all citizens are able to engage in it. Secondly, every citizen is to be eligible to vote and is to be able to stand for office at the ultimately decisive institution, the legislature. Thirdly, the citizenry is to be no temporary electorate, possibly complemented by permanent public opinion polling; rather, politics is to be exercised by the entire people, even if it is done so professionally only by a few and limited to the parliament as the House of Representatives. In a participatory democracy, the general public is a critical institution the entire political sphere has to answer to – not only the government, but also the parliament, the judiciary and the constitutional court.

Let us focus on legislature as an example: similar to the individual state, the world state, too, is in need of a variety of controversies that initiate, prepare and accompany parliamentary debates, and later trigger further amendments if so required. In order to ensure that these discussions actually take place, numerous transnational as well as supranational institutions are required. Without a doubt, a great many international nongovernmental organizations already exist, some of which even have considerable influence. They are in a position to convince (in democracies even to coerce) governments, corporations, and other institutions to enter into a dialogue with the general public and to accept minimum requirements of both a formal and substantial nature. At times, they even manage to organize civil protest across borders. Nevertheless, most of these institutions – the media; political, cultural, and ecclesiastical academies; grass-roots movements; parties and associations – are, so far, still organized 'nationally,' within the confines of a particular individual state. At global level, by contrast, a considerable deficit has to be attested.

In the process of overcoming this deficit and by way of establishing an effective global public, it is important that all the various interests, voices, and languages command roughly the same level of attention. The legal requirements are generally known and uncontested: a global public needs the freedom of the press, the freedom of speech, and the freedom of assembly. These negative freedoms are to be complemented by a positive freedom (of the press), for instance in the form of a press antitrust law. Such measures facilitate the creation of a multitude of competing media, political academies, and grass-roots initiatives. A ban on monopolies, oligopolies, and cartels in other spheres is justifiable only on competitive grounds. In the sphere of the political public, by contrast, additional democracy-promoting reasons can be found: the positive freedom of the press is indispensable for a functioning participatory democracy. A sufficient level of educational attainment is, for the same reason, also required, so as to establish at least a minimum level of literacy among citizens. For cultures that do not rely on written texts, alphabetization is no legal-moral precept per se, but in a world society in which the media play such an influential role it becomes an inevitable constraint.

Yet, even when the negative and positive freedom of the press is secured, the various interests do not even remotely command the same level of public attention. Of the host of dangers that exist I mention only one: the hegemony of a particular language. This follows because a living language is not merely an interest-neutral means of transport. The media of the hegemonic language find a far greater resonance, so that the pictures, symbols, myths, and interests of the accompanying cultural space occupy a privileged position. What is more, cultures that are based on written texts receive much greater weight compared to those of oral provenance.

In individual states, the public is an institutionally varied, if not vague phenomenon: it occurs on different levels, possesses no sharp boundaries, and covers all shades of expertise and impact, from professional academic discourse at one end of the spectrum to the tabloid press at the other. Since the public uses different media and institutions to address and make sense of different subject matter, it exists not in the singular but in the plural, as a colorful bouquet of overlapping publics. Many of them have an aristocratic tendency, in that professional politicians as well as particular media and associations command an overwhelming influence.

World society is, by virtue of its greater size and heterogeneity, greatly marked by these phenomena. The global public is, nevertheless, relatively well developed particularly in areas such as human rights. For there is a global discourse on human rights that is conducted by a heterogeneous intellectual 'community' comprising individual scientists, philosophers, media commentators, human rights organizations, professional associations, the media, and public opinion in important states, as well as relevant conferences and publications. Of similar great significance is the interaction between the high courts. Even states themselves must not to be neglected, because within the United Nations and other international organizations they are the entities that ratify human rights conventions and, in so doing, enable the legislative evolution of human rights on a global level.

No matter how optimistic or pessimistic one's judgment is with regard to the development of a global public, the seventh constructive veto suggests itself in the form of a dependency: as long as there is no effective global public, it is irresponsible to establish a subsidiary and federal world republic.

A global public is indispensable for yet another task: the development of a common political identity that encompasses a consciousness of world citizenship and a critical world memory (see Höffe, 1999/2007: ch. 12.2). The consciousness of world citizenship, in turn, is a prerequisite for global plebiscites. Provided that the notion of worldwide plebiscites and referenda is generally persuasive, it is only defensible if there exists a consciousness of world citizenship as well as a global political public within which the relevant issues are discussed in a thorough and fair manner. Here, too, a threat emerges that requires countermeasures: in order to prevent that the decisions of the six to eight most populous states crush the interests of all others, the example of Switzerland may be followed and a dual majority be demanded: global

plebiscites require a majority by both the states and the world population.

The Danger of Leveling

According to the eighth and final objection that I will discuss here, in times of globalization we face the threat of a leveling that we need to counter with strengthening our particularities, so that the cultural richness of our world and the identity of each individual which is bound to it is maintained.

It is true that many national states and also greater regions have their common history, a particular tradition, culture, and language – or a defined multilingualism – and follow certain shared understandings of how a good communal life is to be organized. States do in fact have a right to that, a right to national particularities and difference. This right substantiates the principle of subsidiarity in the world republic and contradicts the (hyper-)globalist proposal to replace nation-states by a world republic following the model of ancient Rome which downgraded states to provinces of a homogene world empire.

The following constructive veto agrees with the objection, but again only with one third of it: people do have a right to collective particularities like history, tradition, religion, language, culture, and common understandings of the good. Since their plurality increases the wealth of humanity and since the identity of each and everyone depends on them, there exists an interest to take advantage of this right and to counter the danger of leveling that is, for instance, brought about by a culture that acts imperialistic.

According to the second third, the existing states are, however, not an end in themselves. They are units that exist for the sake of human beings. Therefore, they can be combined newly and dissolved for their sake. And according to the last third, neither states nor foreign citizens are released from the commitment to the maxim of the rule of law and democracy. For the purpose of strengthening the relevant principle here, federalism, and countering the danger of a democratic deficit it is called for a dual strategy: on the one hand, one should not unnecessarily hand over responsibilities. The burden of proof lies with the one who demands handing them over. On the other hand, the new authorities and institutions need to be tied to the lower levels. In particular, they need to be accountable to them.

For the legitimation of a democratic world order, there are three strategies at hand. According to the exclusive legitimation through citizens, the world state is established through the will of a global citizens body, which includes the entire world population. Since this strategy appeals to individuals as the agents to whom justification is owed, one might think this strategy to be appropriate. However, against this line of reasoning speaks the right to form and uphold an individual state combined with the fact that the interests of a group, also the ones of a state, are not reducible to the sum of the interests of its members.

Since the nation-states represent the interests of each and every single citizen as well as the interests of the citizenry as a whole, one might argue in favor of an exclusive legitimation through the states. Against this line of reasoning speaks, however, that there are 'cross border' affiliations like religion, language, and profession, sophisticated hobbies and political and social interests that are concentrated by organizations like Amnesty International or Doctors Without Borders. To give an example: one might be German speaking, yet Muslim and Swiss, anyhow chess player and mountaineer.

Consequently, a third combined strategy seems to be apt. According to this strategy, the world republic is legitimized by the citizens as well as the states, and all power of the world state stems from a twofold citizenry: the society of all humans and of all states. This dual strategy needs to be embodied in the organizations of the world republic. In the manner of the draft to the Constitutional Treaty of the European Union, one might call it a 'union of states and peoples.' The highest institution, the world legislator as a world parliament, is to consist of two houses: a World Congress, the representation of the citizens, and a World Senate, the representation of the states. Their exact constitution and the difficulties that may rise from the establishment of greater regions do not need to be of concern for us now. That Liechtenstein is to be given less weight than India or China is evident, but which weight they are given exactly is a matter of political decision making. May be the radical of the inhabitants might be a solution: for one specified unit of inhabitants one is given one vote, for the quadruple number of inhabitants two, for the ninefold three votes and so on.

Conclusion

It is a universal imperative of right, which speaks in favor of a world republic: conflicts between humans shall be solved not by private opinion or violence, but only by law and its protection though the state. In a world republic we are world citizens, cosmopolitans, but not in the exclusive sense of the term as Hegel criticized it (*Elements of the Philosophy of Right*, section 209) that is hostile to nation-states. With a feeling of moral superiority the exclusive cosmopolitan says: I am not German, French, or Polish, but merely a world citizen, a cosmopolitan. In this case the cosmopolitan right replaces the 'national' civil right; one is a cosmopolitan *instead* of being a citizen of an individual state. The complementary world republic steps back from this either/or rhetoric of 'either nation state or cosmopolitan world order.' The civil right of the world republic does not dissolve the national civil right, but supplements it. Furthermore, it adds regional subunits.

There is going to be a new and hitherto unknown multiple citizenship. The longing for this combined with the longing for global peace and global justice might inspire humanity to realize the vision of the world republic: whether one is primarily German, French, or Italian and a citizen of Europe only secondarily will be decided by the democracies of Europe within the next decades. Primarily, however, one is one of the two, secondarily, the other and tertiary, one is a world citizen: a citizen of the subsidiary and federal world republic.

World Systems Theory

Daniel Chirot, University of Washington, Seattle, WA, USA

Abstract

World systems theory (WST) was created by Immanuel Wallerstein in the 1970s, though earlier Marxist theories first proposed similar ideas. WST claims that rich core capitalist societies succeed by exploiting poorer peripheral ones. In between are semiperipheral societies, a precarious global middle class. The periphery therefore can only advance through global revolution that will end the world capitalist system. WST's holistic approach that studies societies in the context of the entire world rather than in isolation is valuable. If freed of its Marxist extremism and questionable economic assumptions that have marginalized it, this approach can help us better understand the nature of social change.

Introduction

The essence of World systems theory (WST) is that the modern world, dominated by capitalism, has since the sixteenth century increasingly become an integrated whole in which single countries cannot be usefully analyzed without placing them within the context of the entire global economic and political system. Though its intellectual antecedents date back to the late nineteenth and early twentieth centuries, WST's contemporary version was pioneered by Immanuel Wallerstein (1974, 1979, 2011) whose goal it has been to overcome narrow disciplinary specialization in the social sciences. In his many works, Wallerstein has sought to explain unequal development and wealth between societies in the modern capitalist world and to understand the cyclical patterns of expansion and contraction that characterize this world system. WST stresses that poorer, or 'peripheral' societies have been systematically underdeveloped by the rich and powerful 'core,' and they stand little chance of prospering without world revolution. Between peripheral and core countries are 'semiperipheral' ones that act as a kind of global middle class stabilizing the world capitalist system, but because semiperipheral countries are subject to the greatest systemic strains, that is where revolutions are most likely.

Wallerstein's vision is strongly Marxist and emphasizes the exploitative nature of capitalism; but instead of relying only on the internal class structures of individual societies, he has theorized that societies as a whole fall into broad categories that mirror the more classical Marxist classes. So, for him, the 'ruling class' in the world capitalist system consists of the ruling classes in the most powerful core countries, and those countries compete among themselves for hegemony. Poorer societies, therefore, are not that way because they are 'underdeveloped' so much as because they are kept poor by the exploitative world capitalist system's core economies. So WST attempts to debunk what is called 'modernization theory,' which claimed that all societies can follow a similar path toward greater economic prosperity and modernity as the one followed earlier by the more advanced Western societies.

Wallerstein has further posited that a world capitalist system can only function smoothly if there is one dominant core power, and that in times when there is conflict between potential hegemonic powers, the system is unstable. This is all the more the case because capitalism is subject to major periodic economic crises, just as Marxists have always claimed.

Because of its ideological radicalism, WST was very appealing when it appeared in the 1970s at a time when American and many other social scientists around the world were trying to understand America's war in Vietnam and the seemingly inexorable rise of world communism. Since then however, WST has been marginalized, especially since the collapse of the Soviet Union and the dramatic changes that have transformed China while bringing it solidly into this world capitalist system. The communist Soviet Union and China (as well as, for a time, North Korea) were the societies Wallerstein looked to as models for the future world socialist system that was supposed to be fairer and more egalitarian than the ruling world capitalist system. He also saw what used to be called 'third worldism,' that is, the rise of radically socialist former colonies and their alliance in an anticore, revolutionary bloc as something that would lead to the collapse of the world capitalist system. Of course, that is now all history, as it has hardly come to pass.

It has to be said that there are very few if any major economists or any serious political scientists who would accept WST's basic premises about how the world economy functions or where it is headed. Despite the obvious return of a major global economic crisis since 2008, only a very small minority of analysts believe that today's economic troubles are likely to lead to worldwide socialism or even to the partial revival of communist nonmarket command economies.

Nevertheless, if WST can be divorced from its ideological bias it has the potential to become a valuable tool for understanding social and political changes. Its emphasis on holistic global analysis and its awareness of the dangers inherent in an unbalanced capitalist world system that lacks a stabilizing hegemonic power have as much relevance as ever. If anything, the world is even more globalized than in the past. Indeed, many of WST's assumptions have been absorbed into work by some sociologists, geographers, ethnographers, and historians. Without resorting to crude Marxist doctrines, this kind of analysis could even offer some interesting ideas about the world economic situation.

The Intellectual History of the Theory

The notion that capitalist growth and therefore successful industrialization can only occur through the ruthless exploitation of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32172-9

an impoverished working class was basic for Karl Marx, but he concentrated primarily on the internal workings of class conflict within rather than between different societies. Nevertheless, Marx also observed that capitalist expansion was a global phenomenon that had a particularly unsettling effect on colonial or semicolonial societies. This became an important aspect of later Marxist theories of international relations. The works of Rosa Luxemburg and V.I. Lenin as well as those of many non-Marxist critics of late-nineteenth and early twentieth century European imperialism stressed the internationally exploitative nature of capitalism and its seeming need to control the ever growing markets and resources. Lenin's theory of *Imperialism* (1939), written in 1916, claimed that World War I was the logical outgrowth of the competition between capitalist powers for colonies, because without the surplus extracted from dependencies, the internal contradictions of capitalism would produce growing worker immiseration and eventually, revolutions. The consequence of this theory, if it were to be believed, would be that revolutions outside the core capitalist societies can deprive the core of easily exploitable human and material resources, and therefore lead to worldwide revolution. This belief remains at the heart of Wallerstein's ideas, except that the direction of class conflict for him is determined by the global struggle between exploiting and exploited societies. For Wallerstein, no revolutionary movement within a single society, or even several of them, can succeed in bringing down capitalism unless it sparks a global revolution.

There is a great irony, therefore, in the fact that WST's other intellectual parent was early twentieth-century right wing nationalism. Joseph Love's work (1996) traces the development of nationalist economic theories of underdevelopment from the German Friedrich List in the nineteenth century, through the Romanian fascist–corporatist Mihail Manoilescu, and to the Latin American right in the 1930s. The relative backwardness of these societies (they were what Wallerstein would call 'semiperipheral' at the time they produced the relevant theorists) was explained mostly by the dominant market position of the most developed capitalist powers of those times, first England, and later, the major West European powers and the United States. The implications were that in order to develop, the poorer societies had to shield themselves from the world market, to somehow exclude that world system. Nationalism justified such policies as essential in order to protect the self-interest and integrity of the less developed nations.

World War II discredited fascist–corporatist notions of development, but the theory retained its attractiveness, and it gradually migrated leftward. In Latin America, Raul Prebsich, Celso Furtado, and Fernando Henrique Cardoso became the chief spokesmen for what came to be called 'Dependency Theory.' The explanation of backwardness remained essentially the same, that the developed capitalist powers impeded the development of those who were more backward. But now it no longer seemed necessary to carry out protectionist theories within the framework of an authoritarian, ultranationalist, fascist–corporatist state (Cardoso and Faletto, 1979). It should be noted that Cardoso, who eventually became Brazil's president, abandoned most of the implications of his theory long before achieving power in his own county. Meanwhile, the theory became increasingly popular within the revolutionary left.

The problem was that a high degree of protectionism in an increasingly powerful and advanced world economy required heavy state intervention to block market forces and popular demand for the consumer goods produced by the world capitalist system. Therefore, some sort of authoritarian, state centralizing mechanism was required to carry out such policies rigorously enough to permit escape from the world system. If the theorists were right, the capitalist core, now led by the United States, would use its economic, diplomatic, and even military power to force open recalcitrant nations. This was the theoretical explanation of American intervention in Vietnam and throughout the Third World. To motivate their people and mount a defense, the leaders of anticapitalist regimes would have to use nationalism as the glue binding their people together in struggle, because they would be unable to provide the kind of consumer rewards offered by world capitalism. For those hostile to right wing, authoritarian nationalism, this led inescapably to the conclusion reached by Wallerstein and his followers, that Leninism in its most autarkic, closed Stalinist or Maoist forms was the only way to protect antisystemic nations until the world revolution achieved its goal of destroying the world capitalist system and replacing it with a more equitable, redistributive world socialist system.

This created an intellectual quandary recognized by many of WST's early followers who did not relish the ideological conclusions reached by Wallerstein and those who remained with him. Could something be saved from the comparative, holistic methodological approach advocated by Wallerstein without having to accept the extreme leftism he and his closest followers, such as Christopher Chase-Dunn (1989), were also promoting? The problem became all the more acute in the late 1980s and 1990s as communism collapsed and Marxism–Leninism was largely discredited throughout the world.

Today, the main challenge to the hegemony of an American dominated world capitalist system comes from the kind of state centered capitalism championed by China that accepts the existence of that system and operates within it, but with a somewhat different set of rules. If China succeeds in its ambitions, in WST terms, it would become a new hegemonic power, but certainly not one eager to end capitalism. On the other hand, the anticapitalist leftist populism of a figure such as Hugo Chavez of Venezuela is so muddled and ad hoc that it hardly presents much of threat to the existing world system.

The Uses of WST as a Supplement to but Not a Substitute for Comparative Economics

Despite its shortcomings, a world systemic approach to the study of social change remains a powerful antidote to narrow specialization. It also addresses problems that will remain with us far into the future, and it offers insights absent in other theoretical models.

While many economists now recognize that perfectly free trade policies imposed on poorer economies may indeed have detrimental effects, and even that the globalization of the late twentieth to early twenty-first centuries may have harmed richer economies, few if any accept the notion that autarky is a reasonable development policy, whatever the type of political regime (Stiglitz, 2006; Amsden, 2007). The import-substitution

policies followed by many Latin American countries from World War II until the 1980s, as well as by India and many other countries, slowed economic growth, led to entrenched, corrupt domestic interest groups that blocked innovation and reform, and ultimately provoked economic and financial crises that threatened economic catastrophe. On the other hand, trade protectionism and developmental policies that fostered export-led industrialization in East Asia produced robust economic growth, and, generally, it is now accepted that working within the capitalist world system but with good governance and sound domestic development policies works well (Ray, 1998; Rodrik, 2003). In contrast, the truly extreme forms of withdrawal from the world capitalist system, that is the autarkic communist states, have all produced economic disasters.

Economic historians have shown that in the nineteenth century, at least, if not before, capitalist development did not rely on colonial markets, so that the economic argument in favor of imperialism turned out to be largely specious (Bairoch, 1993). This brings into doubt yet another of the fundamental assumptions of WST. Yet, no matter what their strengths, there remains something unsatisfying about purely economic models of development.

In the hands of comparativists who place the societies they analyze in a global context and understand capitalism's transformative power, but who also recognize the importance of domestic social structures and the variations caused by specific historical experiences, world systemic ideas help account for some of the differences in rates of economic modernization. Peter Evans (1995) has done this in explaining the success of certain state-led industrialization projects. Though somewhat suspicious of core power, especially American hegemony in the contemporary world capitalist system, Evans recognizes that development within that system remains possible for those who know how to combine effective bureaucratic leadership with local entrepreneurial talent, and who remain oriented to succeeding within the world system and using its advanced technology and market opportunities rather than revolting against capitalism.

Historical studies such as the one by Resat Kasaba (1988) also show how WST can provide important insights as long as it is not used dogmatically. He proves that in the mid-nineteenth century local merchants within the Ottoman Empire were able to use growing trade relations with the capitalist world to strengthen their own position against both the Ottoman state and the interests of the hegemonic core powers. But later, the Ottoman bureaucracy, helped by some powerful foreign, core financial institutions regained its strength, and this reduced the economic power of the domestic merchant class. Far from being 'compradors,' that is, subservient tools of the capitalist core (which is what conventional WST and most Marxists contemptuously call them), these local entrepreneurs might have spearheaded an economic and social modernization that would have made Ottoman society more open, tolerant, and progressive. The world capitalist system did indeed play an important role in peripheralizing late Ottoman society, but not in the expected way, and only because it was successfully manipulated by an increasingly nationalistic, Turkish, anticommercial state elite.

When East-Central European economic histories are compared, it turns out that contact with the growing capitalist world economy centered in northwestern Europe and later Germany did indeed play an important role in the past, but not in the way predicted by WST. The more closely associated these economies were with the core capitalist ones in the past, the more advanced they have been in the modern era, and this holds true to this day (Chirot, 1989; The Economist, 2012).

In other words, it is certainly very useful to take into account a particular society's position in the world capitalist system. Global trade, information, and political networks unquestionably play an important role in how various societies develop. Exploitation of colonial economies did hurt many of them in the long run (Bairoch, 1993). Extracting resources, particularly oil, from countries with weak governance institutions and corrupt power elites clearly sets those peripheral economies back, or at least stymies their economic growth and general prosperity. This is most evident in a number of African cases, but also in oil-rich former Soviet Republics, including Russia. Good comparative studies, however, show that there is no strict causal relationship between being a peripheral resource exporter and slow development. On the contrary, it is the interaction between global position and domestic institutions that is the key to whether or not balanced economic growth occurs (Humphreys et al., 2007).

Long-term business cycles used to be studied by economists, most famously, by Joseph Schumpeter, and more recently by Walt Rostow (American Economic Association, 1944; Rostow, 1971). This tradition practically died out in economics in the late twentieth century. Business cycle theorizing came to be, instead, an attempt to explain away short-term changes, not systemic long-term ones (Hartley et al., 1998). Here, WST and especially Immanuel Wallerstein have taken up the challenge and claimed to see very long-term waves of growth and decline over the many centuries of the world capitalist system. How WST measures and interprets such cycles can be questioned, but it is reasonable to assume that major technological changes over time usher in drastic social and political as well as economic changes. The development of cheaply produced cotton textiles brought about the first phase of the industrial revolution. Subsequent major inventions, from the railroads to the advanced use of chemistry and the technological leap that produced widespread usage of electricity, underlay the rise of Great Britain, then France, Germany, and the United States in the nineteenth and early twentieth century. This was followed by the age of automobiles, then the electronics revolution, and now a transformation just getting under way in communications and the use of biotechnology. At each stage, certain countries led the way and gained power, but each major new technology also unsettled old social institutions and produced crises because of failures to adapt in time. While many analysts might not agree, WST would predict that the world economic crisis that began in 2008 is a function of just such a shift and the failure of both Americans and Europeans to properly adapt, at least so far (Chirot, 2011).

Theoretical Limitations and Methodological Promises

WST's methodological approach reaffirms an old but often neglected concept. All societies have operated within larger

systems, and without placing them in that context, our understanding of how they work is severely limited. There can be no general laws of social behavior that do not take this into account.

Beyond this, WST has shed light on the nature of modernization, even though that is a term it avoids in order to show it rejects the functionalist theories proposed by 'Modernization Theory' in the 1950s and 1960s. WST has shown that there is indeed a capitalist world system, and its rules, largely determined by the core powers, affect everyone. Furthermore, this capitalist world is itself an evolving, changing structure. It is subject to periodic waves of prosperity followed by economic downturns. Even economists need to take such large systemic factors into account in order to perfect their models. So do the other social scientists who, by and large, limit comparisons to discrete cases rather than incorporating system-wide variables.

A world systemic approach to social science, however, must admit the limitations of the theory as it now stands. Aside from its tendency to neglect economic theory, mentioned above, WST has also relegated technology and science to an almost insignificant role. Thus, Wallerstein and most other followers of WST refuse to admit that Western European capitalism's early dynamism depended on the religious and scientific transformations that occurred during the Renaissance, Reformation, and Enlightenment. Max Weber remains a better guide to this process of change than any of the contemporary practitioners of WST, and by neglecting him, and the cultural issues he raised, they have weakened their paradigm.

Ideas generated by the core, from science and technology to various political ideologies such as nationalism and Marxism, have affected the rest of the world as much as the economic and military power of the core. These ideas have been transformed in many ways within the periphery and have stirred up particularly disruptive ideological currents of resentment and antimodernism in what Wallerstein has called the semi-periphery. There is no theoretical reason why WST could not use its model to expand our understanding of how this has worked. In fact, one of Wallerstein's most devoted followers, Georgi Derlugian (2005) has used the analysis of culture as well as more conventional WST to explain the catastrophic developments in much of the Muslim part of the former Soviet Union.

There is no need to continue to adhere to the simplistic materialism so many of its practitioners now follow. Ideas, scientific innovation, and even changing notions of social and political morality, including the unexpected increase in the role of religion throughout much of the world, can be analyzed in world systemic ways to great advantage.

When he first presented his theories, Wallerstein declared himself to be a disciple of Fernand Braudel and the French *Annales* School. That Braudel himself (1979/English translations 1981–84) was influenced by Wallerstein is evident in the vast comparative sweep of entire regions, and ultimately the globe, that he treated as a system of interdependent parts.

In a sense, WST has succeeded well enough in influencing historical studies of social, economic, and political changes that its ideas appear in some very influential, major studies. Some cite Wallerstein directly, while others do not but use ideas and sources influenced by his ideas.

For example, the historian Anthony Reid (1988/1993) has presented a daringly new vision of Southeast Asian economic, cultural, and political history by putting it into the kind of comparative and global perspective that WST has always championed.

Ken Jowitt's analysis of the failed attempt to create a Leninist world system (Jowitt, 1992) also adopts a world systemic approach without admitting it. He points out that the communists actually were more successful at creating a cultural and ideological world system of their own, with a powerful core struggling to keep its peripheries under control, than at creating a system based on economic links. He then predicts that the collapse of Leninism will have a globally destabilizing effect because it will leave the resentful losers in the world capitalist system without any constructive or predictable revolutionary alternative.

More recently, Kenneth Pomeranz (2000) in his pathbreaking explanation of why China fell behind the West, particularly Great Britain, in its economic development has incorporated WST ideas. For him, the explanation does not lie so much in England's development of modern ideas, but rather in the combination of the fortunate placement of its coal and its ability to exploit its colonial empire and domination of international trade routes. To be sure, these conclusions are themselves controversial and can be questioned, but the success of Pomeranz' shows that WST ideas continue to be spreading.

Even a superb recent history textbook by Jane Burbank and Frederick Cooper (2010) incorporates many WST ideas without directly citing Wallerstein. Their book makes the interaction between major empires the key to understanding the history of the modern era.

WST's potential is far from exhausted. Needless to say, many leftist social scientists such as David Harvey (2010) have incorporated WST ideas into their work, but the important point is that this approach has influenced much analytical work that is not specifically on the far left. Flexibly used, it still has lot of new insights to offer, and it is likely that in the twenty-first century, in response to increasing globalization, continuing inequality, uneven prosperity, and worldwide economic crises, it will continue to develop in ways that will take it well beyond its sectarian origins.

Abstract

In anthropology worldview studies have long been linked to a mentalist approach to culture, especially from Boas to Lévi-Strauss, with sophisticated analyses in so-called cognitive anthropology. A modest materialistic view emerged as a critique, with its most powerful elaboration in cross-cultural. Also, an evolutionary view on man–environment emerged, speaking of 'sphere' instead. Applications can be found today in such technical subdisciplines as ethnomathematics.

Finally, with the virtual disappearance of worldview studies in anthropology, the concept is found in philosophy of science and in religious studies.

The Notion of Worldview

The literature on worldviews leaves one with a feeling of uneasiness. On the one hand some philosophers and scholars in religious studies claim that the progressively scattered field of knowledge of the twentieth century points to the importance of worldview as a unifying force for the organization and deployment of scientific research. It would act like a logical theory in the project of Enlightenment. On the other hand, explicit use of the term *worldview* in anthropology is decreasing over the years, to the extent that some have announced the end of it (Beine, 2010).

Hence, presenting a critical assessment of the notion for an encyclopedia is far from easy. This article will focus on the use of worldview in anthropological studies first, and expand from there to a larger interdisciplinary discussion.

Anthropological Studies

Worldview has been associated over a long period with the culturally idealistic approaches in anthropology. Starting with Franz Boas, anthropologists have been working in the perspective of the 'psychic unity of humanity,' meaning that all human beings would share the same basic categories of thought, but also of sentiment and volition. For example, time, space, causality, and such would be universally shared, although particular shapes and contents of them could be distinguished in diverse cultural traditions. In a general sense, this perspective is based on a philosophical program of mentalism: researchers took for granted that 'in the human mind' or 'in immaterial culture' situated in the mind, such categories can be found. Kearney (1984) states, in a rare overview of research on this issue, that this emphasis on the 'mental' across cultural borders is probably due to the close links between linguistics and anthropology in the American case: language structures were presupposed to exist in the mind, and hence by extension all other structures and processes that organize the experiences of an outside world would be situated there too. The encompassing phenomenon, which would synthesize concepts, views, and expectations about the way the world is, is the worldview of a cultural group: a worldview is the shared software of a cultural group, which processes input from the senses, stores its information, and serves as the basis for action for the collectivity (after Kearney, 1984: chapter 2).

Most certainly, Claude Lévi-Strauss reinforced the mentalism in anthropological studies by starting almost exclusively from a linguistic perspective with his structuralist anthropology (Lévi-Strauss, 1958). In his theory, the deep structures, which matter most for the study of any domain of culture in any part of the world, are to be found in the human mind. Their universal form is uncontested in structuralism until the 1980s of the past century. In the view of Lévi-Strauss sense data, concepts, principles, and systems of thought and action are structured logically, much like the data in a computer. In his study of thinking and knowing in non-Western cultures, nor in his systematic comparative analyses of myth Lévi-Strauss questions the mentalist presupposition: in his perspective it is 'all in the mind.' He does not doubt either that the motor function (or the generative force) of the deep structures can be found in the human mind. Thus, in the famous *La pensée sauvage* (1962) the primacy of classification logic in the human 'hardware' is an unquestioned point of departure, which allows the author to sketch human thinking worldwide as the universal mapping and structuring of inputs from external reality into highly comparable worldviews. The differences he finds are interpreted by means of structural nuances, which are reduced to the workings of the very same universal ironclad logic in the mind. In his numerous studies of mythology a similar intellectual move can be perceived: in these very elaborate analyses Lévi-Strauss (1980) tries to show how the same inborn and hence universal logic is at work in the structuring of human imagination throughout the world. In that sense, the structuralist school of Lévi-Strauss illustrates very strongly what Kearney criticizes as a mentalist view on culture. Although Lévi-Strauss hardly ever uses the term *worldview* to indicate the ensuing encompassing structures that he finds (or builds) across cultures, his use of deep structures in the mind of humanity seems to amount to the same effect.

In the period of the 1960s until the 1980s, a similar, but more differentiated, subdiscipline emerged in American anthropology, known as ethnoscience. It grew out of folk taxonomies – a range of subdisciplines from ethnobotany to ethnozoology – and was later generalized to cognitive anthropology. In an overview article by one of the scholars in this branch of anthropology (and linguistics), Werner and

Schoepfle (1987) explain that this approach aims at mapping in a systematic way what amounts to be the knowledge of different cultural traditions. In practice, ethnographers trigger terms and meanings from a set of informants while presupposing that all human beings actually work in their mind with a preconceived (or inborn) classification logic. Doing fieldwork then amounts to 'filling in' by means of the informants the formal structures of classification about different domains of reality that are in themselves unquestioned, because all human minds are believed to work in a rather exclusive way within the frame of universal classification logic. Of course, different informants will be competent in different reality domains. Hence, particular taxonomies will be filled in more by some and less by others. The ethnographer is, in Werner's view, the one who can construct the ideal knowledge system that is the sum of all competent data and classification thinking in one particular cultural group. Werner calls this the 'synthetic informant model' or SIM: it holds the knowledge of the 'omniscient informant.' No one member of a community has the total classification system of knowledge, all terms, and all concepts that are formulated in the model. Only the virtual 'omniscient informant,' built up as a product of research with many particular informants, adding on bits and pieces along the way, will constitute the overview of knowledge available in the community. The anthropologist thus constructs a sort of superstructure of worldview items that is supposed to represent all partial worldview items in real and particular members of the community. The SIM is warranted, according to the researchers, because it synthesizes in an encompassing model what is present in a scattered way throughout individual cultural subjects. This thought is intriguing, since it carries to its limit the a prioris that I indicated in Lévi-Strauss's approach. Based on the presupposition of the universality of taxonomic thinking as the preferential or even unique way of mapping reality, the 'omniscient informant' of SIM thus becomes something like the necessary and natural 'omniscient informant' of SIM, and thus becomes something like the necessary and master discourse for a community. Although not one person in any particular community will actually incorporate the model, the anthropologist pretends that the construct as SIM would be warranted and truthful because it would be the most encompassing instantiation of the deep logic at work. It is clear that this approach carries the philosophical idealism of former scholars to an extreme: actual flaws and patchwork patterns in empirical work do not hinder the scholar because the deep structure logic that the researcher projects into human worldviews guarantees the validity of the virtual model.

Over the years critical assessments have been developed, yielding more varied and nuanced descriptions and models. On the one hand, different logics have been recognized in non-Western cultures, e.g., inference next to classification logic. Thorough experimental work has been done (e.g., Cole, 1996). On the other hand, knowledge and learning have been looked at much more as contextualized processes. This made for perspectives on worldviews as differentiated and dynamic ways of production and use of knowledge, rather than fixed or inborn software structures (Lave, 1990). Hence, the worldview as such is not the focus of attention, but rather the processes of acquisition, production, use and change of data, models, and folk theories. Along the way, the term *worldview* silently disappeared from the anthropological literature. A quick survey of textbooks over the past decade teaches us that almost none of them mention the concept in their index. A rare exception is Bonvillain (2006), who uses the term exclusively in the context of struggles by minorities to claim their rights in a context of marginalization: "[Worldview is the] culture-based, often ethnocentric, way that people see the world and other peoples." (Bonvillain, 2006: 35).

However, a second approach should be mentioned. It is the materialistic view on culture (in the line of M. Harris and a small group of Marxists) elaborated by Kearney. In his book on worldview, Kearney (1984) explicitly turns against the philosophically idealist approach focused on in the previous sections of the present contribution. Although he dwells on historical roots most of the time (Boas and others) and is limited in his scope to work before 1980, he makes a deep critique of the mentalism in most of the old work, which is largely valid for the broader cognitive anthropological studies of a later date.

Kearney refers succinctly to the work of the Russian psychologist Vygotsky. The so-called sociohistorical approach of this early Marxist psychologist was an example of situating thinking, and hence worldview, in sociohistorical contexts. With a school of researchers (Luria, Leontiev, and many others, see Wertsch, 1990), Vygotsky developed an approach on the cognitive world that emphasized social functions as well as the practical workings of concepts, models, and worldview. Kearney picks this up and develops a materialistic theory on worldview that recognizes static aspects (like classification systems) but at the same time looks at subjects in their manifold interrelatedness: they are related to their self, and to others. On top of that they are, through learning processes, related to concepts and pragmatic procedures that are transferred by groups or communities: notions of dealing with time, space, causality, and so on. Kearney emphasizes that the ecological environment has impact on worldviews as well, for example, cosmological processes induce views about time, while the daily experience of the geographical environment will serve as foundation for a 'carpentered space' (in the Western worldview, see Campbell, 1989) or else a 'habitat lifespace' in some oral traditions (Pinxten et al., 1983).

What Kearney did not know, apparently, is that the Vygotsky school became very influential in the West, basically by the rediscovery, translation, and subsequent introduction in the Anglo-Saxon world of his writings and a lot of the publications of his collaborators by scholars such as J. Wertsch and M. Cole. Not only did a series of books get translated and discussed but at least two English language journals were launched (*Activity, Mind and Society* and *Culture & Psychology*). Moreover, a whole network of groups and institutional programs was developed in the past two decades, stretching from Russia over Europe to the United States and Japan. So, although Kearney's proposal to work out a materialistic perspective on worldview, with links to the early Marxist psychology of Vygotsky, was not picked up in anthropology, a strong group of psychologists now work out a materialistic view, combining cognition, culture,

and an action perspective in thorough and cross-culturally oriented research. However, the notion of worldview, still so central in Kearney's book, is not used anymore in this line of 'cultural psychology' (which is the actual title of Cole, 1996). Rather, the focus is on types of activity, types of contexts, mathematical skills, time (e.g., Vaalsiner, 2006), and so on.

Worldview and Sphere

A special case of recent date is the work of T. Ingold. This influential and prolific anthropologist combines an evolutionary approach with a deep interest in an environmental focus on culture and learning. The old work of ecologists such as von Uexkühl, von Bertalanffy, and others studied social and cultural patterns and forms in the ecological context of the subjects. The term *worldview* is seldom used, but such concepts as 'Umwelt' or ecosystem seem to be conceptually similar or overlapping with what was understood by worldview in the social sciences and philosophy. The fact that these authors came from biological sciences may account for not having them brought into contact with the worldview perspective of the humanities. *The Perception of the Environment* by Ingold (2004) is, in my view, the one great exception of recent date in that respect. Ingold did thorough ethnographic research with the Saami people in Finland. In this major book, he expands his scope to encompass all hunter-gatherer cultures. A central issue he introduces has to do with cosmology, or the broader notion of 'worldview' (without using the term in any central way). Ingold explains how hunter-gatherer peoples live within nature, whereas at least Western peasant cultures share a worldview of humans living vis-à-vis nature. The latter have an objectifying view: humans look upon all other creatures as if from an outsider position. Ingold examines how the globalization discourse of today's social sciences can only be developed and even understood in this latter worldview: the whole world is constructed as the context that exists outside of human beings, and hence the natural environment is seen as a globe by humans, who distance themselves from it by conceiving as a whole existing independent and outside of the observer. In the worldview of hunter-gatherers, the environment is seen as a sphere, that is to say an environment that is like a habitat, with all creatures (including humans) living within the whole. The consequences of these different stands on nature or environment are tremendous: in the hunter-gatherer culture humans see themselves on an equal level with animals and other natural phenomena, as is shown in the 'discourse' between animals and humans in such cultures (e.g., illustrated in the rock paintings and drawings Ingold discusses). In the Western view on reality as a globe, humans see the environment as the objective other, which is somehow estranged from human beings and can hence be manipulated by them. My reading of this new line of research is that, by linking the cultural and social anthropological models (again) with the broader ecological perspective, Ingold in fact opens up a new line of thinking on worldview.

Applications

Ingold did link his approach to culture with natural sciences, especially with biology. On the other hand, in the work cited as well as elsewhere (Ingold, 2010) he shows a keen interest in the production and use of artifacts, including what is generally referred to as art. In that sense he allows for applied anthropology to be linked with worldview. In a very specialized field, outside of anthropology, this interdisciplinary link between the worldview focus and applied anthropology is booming in recent research (of the first and second decade of this twenty-first century). In what is now known as ethnomathematics – linked in name and by means of some researchers in that field with the cognitive anthropological approach, but mainly emanating from mathematics education circles – the relevance of worldview is keenly discussed. The founding father of this subdiscipline, the Brazilian mathematician U. D'Ambrosio (1985) has made multiple references to the living conditions, the cultural practices and beliefs, the social aspects of schooling and of learning in general, and how all of these impact the success or failure of mathematics education.

A group of sociologists and anthropologists carried out research in the same perspective. One of the influential scholars in this regard is the Danish mathematician Skovsmose who successfully launched the concepts of 'background knowledge' (BK) and 'foreground knowledge' (FK) (Skovsmose, 1994). BK refers to the preschool knowledge a child brings to school from her culture: concepts and models about reality, linguistic categories, learning styles, and strategies to build and use knowledge. FK then encompasses all those concepts and skills the teacher can add on to the BK of each child to introduce it by means of insightful and relevant (to the child) steps to a further level of formal thought. Here again the notion of 'worldview' as such is hardly ever used in the literature. But to my mind the combination of BK and FK seems to add up to the content of what researchers in the humanities and the social sciences understood by worldview (Pinxten and François, 2011). The whole engagement with ethnomathematics is to understand what formal thought (and mathematical thinking as an integral part of it) amounts to in different traditions of thinking and learning. From this knowledge the mathematics educator will then try to develop learning procedures and curriculum material that will allow an opportunity to counter the serious dropout rates of minority groups and lower social groups.

Religion, Ideology, and Worldview

In the past decades the concept of worldview is abundantly and almost exclusively used in religious contexts. Not surprisingly it then also has a normative ring.

Already in the Marxist perspective on worldview, which was introduced by Kearney (1984) action and action strategies were an integral part of the concept (his Chapter 2). That focus broke away from the purely objectifying 'idealist' view of structuralists and cognitive anthropologists. In a broader philosophical view we find worldview linked with the old German notion of *Weltanschauung*, with a decidedly normative aspect: it refers

to the way the world is known and is (to be) interacted with. Most scholars refer to Wilhelm von Humboldt (1767–35) as the originator of this notion. Today, philosophers and scholars in religious studies continue on this line of research. Thus, the well-known scholar in comparative study of religion Ninian Smart gives it a central place in his study on human beliefs (Smart, 2000), while other Christian scholars diminish the role of the cognitive or knowledge dimension of worldview in order to underline the prominence of religious and existential dimensions. Thus Sire (2004) states that worldview is "a commitment, a fundamental orientation of the heart, that can be expressed as a story or a set of presuppositions (assumptions which may be true, partially true, or entirely false) which we hold (consciously or subconsciously, consistently or inconsistently) about the construction of reality, and that proved the foundation on which we live and move and have our being" (Sire, 2004: 15–16).

The conservative philosopher of science and of religion McGrath (2004) approvingly cites MacIntyre in his disbelief about the project of Enlightenment and calls for a reuse of a worldview notion that includes knowledge but places it firmly in a broader, not only rational but clearly religious (Christian), foundation.

Whatever the chances for success may be for such a re-emergence of a religious worldview notion, the general criticism on a detached and purely cognitive perspective on worldview and knowledge has been picked up by numerous religious scholars outside of anthropology.

An interesting research group of the past decades was started by the Belgian philosopher and logician Leo Apostel. He was trained by the philosopher of rhetoric Chaim Perelman and by the logician Rudolph Carnap. From the latter's Vienna Circle work he borrowed the ideal of a 'unified science.' Apostel worked extensively with Jean Piaget, adopting the focus on logically coherent development of knowledge from him. Finally, he was close to the research group of Ilya Prigogine, who combined ontological interests with thermodynamics. Apostel embraced some of the criticism on Enlightenment thinking and started out to work on an ethically responsible approach to science (parallel to I. Stengers, M. Serres, B. Latour, and others today). This critical position did not reject rationality or a strongly scientific approach to knowledge but looked at science as a form of contextualized thinking and acting. Apostel engaged in extensive collaborative research with scholars from different disciplines and also took care to involve researchers from various life stance and religious positions. In the course of this work he developed the idea that scientific knowledge was too scattered and hence vulnerable to particular and even particularistic interests. At the same time the group around Apostel recognized that science is produced by human beings (taking in the criticism by Kuhn, 1962, and sociologists of science) and that the latter were in need of a synthetic and self-critical worldview to found their intuitions and heuristics. He founded a research center at the Free University of Brussels (the Center Leo Apostel), which is entirely devoted to the study of worldviews in philosophy and science. He thus merged the 'unified science' ideal of the Vienna Circle with the pluralistic and interdisciplinary approach he explored in the 1970s and 1980s of the past century. In one of his last publications (Apostel and Vanderveken, 1991) the project is outlined as a major research program for the whole of science, recognizing at the same time that science is a human endeavor and thus in need of more than only rationalistic principles. In a sense, the criticism on Enlightenment thinking by conservative thinkers and religious scholars (such as McGrath) is taken up as a fair critique. It is answered by the exploratory research in worldviews: a new, scientifically screened and tested worldview is needed, according the group, in order to overcome the failures and inconsistencies of the old Enlightenment project. The center was successful in attracting research grants, producing PhDs, and publishing worldwide. It certainly acquired a high status by organizing a series of pathbreaking symposia, followed by an intriguing book series with a first-class academic publisher, under the inviting title Einstein Meets *Magritte*. The series title in itself highlights the programmatic perspective of the worldview group in Brussels: both science and art, both cognition and vision. Over the years a plethora of great names has become attached to the initiatives of this group, all of them engaging themselves with the worldview notion in one way or another (e.g., see Aerts et al., 2005).

Whether the program will be successful in the end is an open question. It is relevant here to mention the initiative since it focuses squarely and uniquely on worldview. In their perspective science needs a unifying worldview today. This worldview will certainly be cognitive but does entail ontological, religious-moral, and political stands as well. Because scientific rigor is combined with societal engagement, it presents an intriguing positive alternative to the merely ideological worldview concepts of the religions. In that sense the Brussels worldview program is linked with the older anthropological perspective (explicit use is made of anthropological material, but also of the contemporary sociology and ethnography of science with Latour and others, Apostel and Vanderveken, 1991). On the other hand the ecological and evolutionary thinkers (e.g., von Bertalanffy) as well as genetic psychologists (e.g., Piaget) are recognized as foundational for the contemporary project. A question that remains is to what extent the group is aware and critical of the transcendental implications of former philosophies of science (such as Kant and others) and is able to break away from that deep-seated pretention and move to a genuine comparative and possibly pluralistic perspective on worldview (see Aerts et al., 2005, 2011; Note et al., 2009; Vanderbeken et al., 2011).

Conclusion

In this article one finds a short introduction to the notion of worldview in anthropology. The use of this notion as it were stopped after structuralism. Except for the original but rather unique views of Ingold, the perspective as such seems to have become absent from the discipline. The Marxist interpretation of worldview is essential in Kearney's work and is somewhat differently continued in the Western follow-up of Vygotsky's school in what is now called 'cultural psychology.' More ideological positions with explicit use of the term *worldview* will be found today in religious documents. Finally, a single interdisciplinary group, emerging from philosophy, takes worldview as its primary focus (Apostel).

Abstract

Sewall Wright was the leading US population and evolutionary geneticist. Along with R. A. Fisher, he converted breeding into a quantitative science. With his coefficient of inbreeding, now standard textbook material, he provided a simple algorithm for measuring the genetic consequences of inbreeding. In evolution, in addition to developing much of the theory of quantitative population genetics, he advocated his 'shifting balance theory.' He visualized a large population, broken up into partially isolated subgroups, within which random changes of gene frequencies could occur. Occasionally, such a subpopulation would drift into a state of higher fitness, whereupon it would increase and send migrants to upgrade the whole population. He viewed this as the best way for a population to bypass the evolutionary dilemma of not being able to go from one highly adapted state to a higher one without passing through maladapted intermediates. Wright's most important contribution to statistics is the method of path analysis, by which standardized partial regression coefficients are used to measure the relative strength of causal pathways. This is his major contribution to the social sciences.

Sewall Wright was born 21 December 1889, in Melrose, Massachusetts, and died in Madison, Wisconsin, 3 March 1988. Before his third birthday, the family moved to Galesburg, Illinois, where his father, Phillip G. Wright, had accepted a teaching position at Lombard College. Wright graduated from Lombard College in 1911 and, after a year at the University of Illinois, went to Harvard University as a student of William E. Castle. After receiving the doctorate in 1915, he was employed as senior animal husbandryman by the US Department of Agriculture (USDA) in Beltsville, Maryland. He remained there until 1925, when he accepted a position as Professor at the University of Chicago. Upon retirement in 1954 he moved to the University of Wisconsin, where he stayed for the rest of his long life. Wright remained intellectually and physically active until his death at age 98, caused by his slipping on an icy sidewalk during one of his regular long walks.

Early Life

Wright was a precocious child. He could read and kept a diary before starting school. He also learned arithmetic and astonished his first-grade teacher by extracting cube roots. Later he and his brothers printed the first poems of Carl Sandburg, who was a student in their father's composition class. At Lombard he took several courses from his father, including calculus. But, despite his later reputation as a formidable mathematician, Wright never took advanced courses; his mathematics was largely self-taught. His interest in genetics was kindled by reading Punnett's article on Mendelism in the Encyclopedia Britannica.

Between his junior and senior years of college, he used his mathematical and surveying skills to work on a railroad construction in the Standing Rock Reservation in South Dakota. It was an exciting time for him. In his 90s he enjoyed telling about the rough frontier life with cowboys, Indians, and outlaws, and he still recalled a large number of words in the Sioux dialect. This work was cut short by a lung infection. While confined to a caboose, he used the time to study Tait's book on quaternions. As a result of the damaged lung, he later had trouble getting life insurance, something that he found increasingly amusing as he continued to live far beyond the usual life-expectancy.

Wright's father, Philip, was a man of many talents. He taught courses in astronomy, mathematics, economics, surveying, English composition, and physical education. He loved poetry and music, and was disappointed that his son did not take to them. Later he moved to the Brookings Institute where he published a number of books on economics. Wright had two brothers who also attained distinction. Quincy became a leader in international law and Theodore was an aeronautical engineer and acting president of Cornell University.

A full length biography of Wright is available (Provine, 1986), with full details of his life and scientific accomplishments. His scientific papers span the period from 1912 to 1988, an astonishing 76 years. His bibliography comprises more than 200 articles, including a four volume set published during his retirement (Wright, 1968–78).

Animal Breeding

Wright's thesis at Harvard analyzed interaction of coat colors in guinea pigs, a subject which he pursued throughout his USDA and Chicago years. He enjoyed guinea pigs and spent many hours taking care of them. Only the non-availability of an animal house prevented his continuing this after his move to Wisconsin. While at Harvard, he also began his theoretical studies of population genetics. On moving to the USDA, he inherited a colony of guinea pigs that had been inbred for many generations. His analysis of the effects of inbreeding and crossbreeding set a standard for careful analysis; the paper could be written today with hardly a word changed. During this time he invented the inbreeding coefficient, with a simple algorithm now standard textbook material (Wright, 1922a). Also during this period, he formulated the basic principles for analysis of quantitative traits. Wright, along with R. A. Fisher (*see* Fisher,

Ronald A (1890–1962)), converted animal breeding into a quantitative science.

Wright was especially proficient in manipulating correlation and regression coefficients. One of his earliest papers (Wright, 1917) foreshadowed the analysis of covariance. His major statistical contribution was developing the method of path analysis. This is a way of measuring the relative contribution of different causal paths to a quantity of interest, such as size or performance. This was presented in a diagram in which causal paths were designated by arrows and correlations by curved, two-headed arrows (Wright, 1921). A path coefficient, measuring the influence of a path, is a standardized partial regression coefficient. Wright formulated a set of simple rules that made the analysis easy to apply. This method enjoyed great popularity among livestock breeders, although recently it has been largely replaced by more sophisticated, computer-driven techniques that permit analysis of large bodies of data, and measurement of the precision of the estimates.

The technique is most useful for nonexperimental situations and in recent years has found its greatest use in the social sciences. Wright himself used the method in the late teens to analyse 510 correlations of 42 variables involving corn yields and prices and hog production. He could not get this monumental paper published because an animal husbandryman was not supposed to know about economics. It was not published until several years later, and only after the intervention of Henry A. Wallace, son of the then Secretary of Agriculture.

Evolution

After moving to Chicago, Wright changed his emphasis from animal breeding to evolution, although he still retained his interest in the physiological genetics of guinea pigs. Three people, R. A. Fisher (1929) and J. B. S. Haldane (1932) in Britain, and Sewall Wright (1931) in the USA are mainly responsible for the 'new synthesis,' the welding of Mendelian inheritance and Darwinian natural selection into a coherent mathematical theory. Wright's particular contribution was the 'shifting balance theory.' He thought that a major difficulty in evolution was the frequent inability of a well-adapted organism to evolve into a better adapted one without passing through maladaptive intermediates. In Wright's metaphor, a population at an adaptive peak could not move to a higher peak without passing through less well adapted intermediate stages.

Wright thought that a way out of this dilemma was to have a population broken up into partially isolated subgroups. Within a small subgroup random gene-frequency changes can occur and occasionally these may produce a combination of genes that is close to that of the genotypes at the higher peak. Then, selection could take over and carry the population to the peak. This highly adapted subpopulation would then expand and send migrants to upgrade the whole population, and the process could start over.

Wright's theory became very popular among biologists. Its emphasis on gene interactions and its offering a way of putting together adaptive combinations of genes that might be deleterious in other combinations had a wide appeal. On the other hand, the theory was less popular with mathematical theorists. Wright's model required a delicate balance of population size, selection, and migration, which would be rare. It also required that the population spend much of its time, during the trial and error period, in a less than optimally adapted state. Finally, there is a question as to whether the theory is really needed; perhaps mass selection usually suffices for adaptive evolution.

Wright's theory was steadily refined during the rest of his life, but the essence remained unchanged. The theory became almost an obsession with him and he delivered many talks on the subject and wrote paper after paper. It is fair to say that, as to the importance of his theory, the jury is still out. Wright's latest paper (1988) was spirited defense of his idea, while still noting the importance of the contributions of Fisher and Haldane, and of Kimura (*see* Kimura, Motoo (1924–94)) who argued for the importance of mutation-driven, neutral evolution of molecular differences. He concluded that 'all are valid.'

Retirement Years

After moving to Wisconsin, Wright spent the first few years finishing the analysis of his extensive guinea pig studies. These were masterful analyses, but by that time the molecular revolution had changed the nature of developmental genetics, and Wright's methods were out of vogue. When this was completed, in his 70s he began his monumental four volume set, the last volume of which was published when he was 88 (Wright, 1968–78). Although his shifting balance theory is conspicuous throughout, the book is far more than this. It summarizes, in four densely packed volumes, not only his life's work, but the whole field of population genetics. For the last decade of his life Wright's eyesight became progressively worse, and he used a reader that projected a greatly enlarged picture onto a television screen. He continued to read and to enjoy conversations, but in his last years he found it increasingly difficult to keep up with molecular advances and turned more to reading history and biography.

As a person, Wright was quiet, shy, and introverted. He had no small talk, and was hard to converse with. Yet, once the conversation turned to a subject on which he had an interest – and there were many – he could go on at great length. His lectures were always full of details and regularly ran overtime. He had a charming sense of humor and was excessively generous with his time. His students and colleagues held him in great affection.

Social Sciences and Philosophy

Wright's greatest influence in the social sciences is his method of path analysis. It was taken up by several social scientists, such as Dudley Duncan in sociology and Arthur Goldberger in economics, and has become a standard part of the statistical methodology. One of Wright's earliest applications of path analysis used adopted children to separate genetic from environmental influences on IQ scores, and there have been many follow-up studies extending his methods to more complex analyses of behavioral traits with better data. Finally, with the increasing interest in behavioral evolution, especially

among psychologists, mathematical theories of evolution are becoming increasingly common and Wright takes a place in this, along with Fisher and Haldane.

Wright was unusual among biologists in taking an active interest in philosophy. He had a somewhat Leibnitzian view. He disliked any idea of emergence. He found no sharp borders between different levels of complexity, such as between embryo and adult or between mind and no mind. Thus if the mind does not emerge by magic, it must trace its development into a continuous process back to the embryo, the egg and sperm, and ultimately the DNA molecules. He called his concept 'dual-aspect panpsychism.' Mind is everywhere; so is matter.

The biological community either disagreed with Wright's view, or was indifferent. Most regarded mind as a natural outgrowth of appropriately organized matter. Wright held on to his dualistic view, however, and found a few kindred spirits among philosophers, particular his long time colleague at the University of Chicago, Charles Hartshorne.

Abstract

Writing – a system of graphic marks representing the units of a specific language – was invented independently in the Near East, China, and Mesoamerica. The cuneiform script, created in Mesopotamia, present-day Iraq, c. 3200 BC, was the first form of writing. It is also the only writing system that can be traced to its earliest prehistoric origin. This antecedent of the cuneiform script was a system of counting and recording goods with clay tokens. The evolution of writing from tokens to pictography, syllabary (written symbols representing syllables), and alphabet illustrates the development of information processing to deal with larger amounts of data in ever greater abstraction.

The three writing systems that developed independently in the Near East, China, and Mesoamerica shared a remarkable stability. Each preserved over millennia features characteristic of their original prototypes. The Mesopotamian cuneiform script can be traced furthest back into prehistory to an eighth millennium BCE counting system using clay tokens of multiple shapes. The development from tokens to script reveals that writing emerged from counting and accounting. Writing was used exclusively for accounting until the third millennium BCE, when the Sumerian concern for the afterlife paved the way to literature by using writing for funerary inscriptions. The evolution from tokens to script also documents a steady progression in abstracting data, from one-to-one correspondence with three-dimensional tangible tokens, to two-dimensional pictures, the invention of abstract numbers and phonetic syllabic signs, and finally, in the second millennium BCE, the ultimate abstraction of sound and meaning with the representation of phonemes by the letters of the alphabet.

Writing is humankind's principal technology for collecting, manipulating, storing, retrieving, communicating, and disseminating information. Writing may have been invented independently three times in different parts of the world: in the Near East, China, and Mesoamerica. In what concerns this last script, it is still obscure how symbols and glyphs used by the Olmecs, whose culture flourished along the Gulf of Mexico c. 600–500 BCE, reappeared in the classical Maya art and writing of 250–900 CE as well as in other Mesoamerican cultures (Marcus, 1992). The earliest Chinese inscriptions, dated to the Shang Dynasty, c. 1400–1200 BCE, consist of oracle texts engraved on animal bones and turtle shells (Bagley, 2004). The highly abstract and standardized signs suggest prior developments, which are presently undocumented.

Of these three writing systems, therefore, only the earliest, the Mesopotamian cuneiform script, invented in Sumer, present-day Iraq, c. 3200 BCE, can be traced without any discontinuity over a period of 10 000 years, from a prehistoric antecedent to the present-day alphabet. Its evolution is divided into four phases: (1) clay tokens representing units of goods were used for accounting (8000–3500 BCE); (2) the three-dimensional tokens were transformed into two-dimensional pictographic signs, and like the former tokens, the pictographic script served exclusively for accounting (3500–3000 BCE); (3) phonetic signs, introduced to transcribe the name of individuals, marked the turning point when writing started emulating spoken language and, as a result, became applicable to all fields of human experience (3000–1500 BCE); and (4) with two dozen letters, each standing for a single sound of voice, the alphabet perfected the rendition of speech. After ideography, logography, and syllabaries, the alphabet represents a further segmentation of meaning.

Tokens as Precursor of Writing

The direct antecedent of the Mesopotamian script was a recording device consisting of clay tokens of multiple shapes (Schmandt-Besserat, 1996). The artifacts, mostly of geometric forms, such as cones, spheres, disks, cylinders, and ovoids, have been recovered from archaeological sites dating 8000–3000 BCE (**Figure 1**). The tokens, used as counters to keep track of goods, were the earliest code – a system of signs for transmitting information. Each token shape was semantic, referring to a particular unit of merchandise. For example, a cone and a sphere stood, respectively, for a small and a large measure of grain, and ovoids represented jars of oil. The repertory of some 300 types of counters made it feasible to manipulate and store information on multiple categories of goods (Schmandt-Besserat, 1992).

The token system had little in common with the spoken language except that, like a word, a token stood for one concept. Unlike speech, tokens were restricted to one type of information only, namely real goods. Unlike spoken language,

Figure 1 Envelope, tokens, and corresponding markings from Susa, Iran. Courtesy Musée du Louvre, Département des Antiquités Orientales.

the token system made no use of syntax. That is to say, their meaning was independent of their placement order. Three cones and three ovoids, scattered in any way, were to be translated 'three baskets of grain, three jars of oil.' Furthermore, the fact that the same token shapes were used in a large area of the Near East, where many dialects would have been spoken, shows that the counters were not based on phonetics. Therefore, the goods they represented were expressed in multiple languages. The token system showed the number of units of merchandise in one-to-one correspondence, in other words, the number of tokens matched the number of units counted: x jars of oil were represented by x ovoids. Repeating 'jar of oil' x times in order to express plurality is unlike spoken language.

Pictography: Writing as Accounting Device

After four millennia, the token system led to writing. The transition from counters to script took place simultaneously in Sumer and Elam, present-day western Iran when, around 3500 BCE, Elam was under Sumerian domination. It occurred when tokens, probably representing a debt, were stored in envelopes until payment. These envelopes made of clay in the shape of a hollow ball had the disadvantage of hiding the tokens held inside. Some accountants, therefore, impressed the tokens on the surface of the envelope before enclosing them inside, so that the shape and number of counters held inside could be verified at all times (Figure 1). These markings were the first signs of writing. The metamorphosis from three-dimensional artifacts to two-dimensional markings did not affect the semantic principle of the system. The significance of the markings on the outside of the envelopes was identical to that of the tokens held inside.

About 3200 BC, once the system of impressed signs was understood, clay tablets – solid cushion-shaped clay artifacts bearing the impressions of tokens – replaced the envelopes filled with tokens. The impression of a cone and a sphere token, representing measures of grain, resulted, respectively, in a wedge and a circular marking, which bore the same meaning as the tokens they signified (Figure 2). They were ideograms – signs representing one concept. The impressed tablets continued to be used exclusively to record quantities of goods received or disbursed. They still expressed plurality in one-to-one correspondence.

Pictographs – signs representing tokens traced with a stylus rather than impressed – appeared about 3100 BCE. These pictographs referring to goods mark an important step in the evolution of writing because they were never repeated in one-to-one correspondence to express numerosity. Besides them, numerals – signs representing plurality – indicated the quantity of units recorded. For example, '33 jars of oil' were shown by the incised pictographic sign 'jar of oil,' preceded by three impressed circles and three wedges, the numerals standing, respectively, for '10' and '1' (Figure 3). The symbols for numerals were not new. They were the impressions of cones and spheres formerly representing measures of grain, which then had acquired a second, abstract, and numerical meaning. The invention of numerals meant a considerable economy of signs since 33 jars of oil could be written with 7 rather than 33 markings.

In sum, in its first phase, writing remained mostly a mere extension of the former token system. Although the tokens underwent formal transformations from three- to two-dimensional and from impressed markings to signs traced with a stylus, the symbolism remained fundamentally the same. Like the archaic counters, the tablets were used exclusively for accounting (Nissen and Heine, 2009). This was also the case when a stylus, made of a reed with a triangular end, gave to the signs the wedge-shaped 'cuneiform' appearance (Figure 4). In all these instances, the medium changed in form but not in content. The only major departure from the token system consisted in the creation of two distinct types of signs: incised pictographs and impressed numerals. This combination of signs initiated the semantic division between the item counted and number.

Logography: Shift from Visual to Aural

About 3000 BCE, the creation of phonetic signs – signs representing the sounds of speech – marks the second phase in the evolution of Mesopotamian writing, when, finally, the medium parted from its token antecedent in order to emulate spoken language. As a result, writing shifted from a conceptual framework

of real goods to the world of speech sounds (Malafouris, 2010). It shifted from the visual to the aural world.

With state formation, new regulations required that the names of the individuals who generated or received registered merchandise were entered on the tablets. The personal names were transcribed by the mean of logograms – signs representing a word in a particular tongue. Logograms were easily drawn pictures of words with a sound close to that desired (e.g., in English the name Neil could be written with a sign showing bent knees 'kneel'). Because Sumerian was mostly a monosyllabic language, the logograms had a syllabic value. A syllable is a unit of spoken language consisting of one or more vowel sounds, alone, or with one or more consonants. When a name required several phonetic units, they were assembled in a rebus fashion. A typical Sumerian name 'An Gives Life' combined a star, the logogram for An, god of heaven, and an arrow, because the words for 'arrow' and 'life' were homonyms. The verb was not transcribed, but inferred, which was easy because the name was common.

Phonetic signs allowed writing to break away from accounting. Inscriptions on stone seals or metal vessels deposited in tombs of the 'Royal Cemetery' of Ur, c. 2700–2600 BCE, are among the first texts that did not deal with merchandise, did not include numerals, and were entirely phonetic (Schmandt-Besserat, 2007). The inscriptions consisted merely of a personal name, 'Meskalamdug,' or a name and a title, 'Puabi, Queen' (Figure 5). Presumably, these funerary texts were meant to immortalize the name of the deceased, thereby, according to Sumerian creed, ensuring them of eternal life. Other funerary inscriptions further advanced the emancipation of writing. For example, statues depicting the features of an individual bore increasingly longer inscriptions. After the name and title of the deceased followed patronymics, the name of a temple or a god to whom the statue was dedicated, and in some cases, a plea for life after death, including a verb. These inscriptions introduced syntax, thus bringing writing yet one step closer to speech.

After 2600–2500 BCE, the Sumerian script became a complex system of ideograms mixed more and more frequently with phonetic signs. The resulting syllabary – system of phonetic signs expressing syllables – further modeled writing on to spoken language (Rogers, 2005). With a repertory of about 400 signs, the script could express any topic of human endeavor. Some of the earliest syllabic texts were royal inscriptions, and religious, magic, and literary texts.

The second phase in the evolution of the Mesopotamian script, characterized by the creation of phonetic signs, not only resulted in the parting of writing from accounting but also its spreading out of Sumer to neighboring regions. The first Egyptian inscriptions, dated to the late fourth millennium BCE, belonged to royal tombs (Baines, 2007). They consisted of ivory labels and ceremonial artifacts such as maces and palettes bearing personal names, written phonetically as a rebus, visibly imitating Sumer. For example, the Palette of Narmer bears hieroglyphs identifying the name and title of the Pharaoh, his attendants, and the smitten enemies. Phonetic signs to transcribe personal names, therefore, created an avenue for writing to spread outside of Mesopotamia. This explains why the Egyptian script was instantaneously phonetic. It also explains why the Egyptians never borrowed Sumerian signs. Their repertory consisted of hieroglyphs representing items familiar in the Egyptian culture that evoked sounds in their own tongue.

The phonetic transcription of personal names also played an important role in the dissemination of writing to the Indus Valley where, during a period of increased contact with Mesopotamia, c. 2500 BCE, writing appears on seals featuring individuals' names and titles (Parpola, 1994). In turn, the Sumerian cuneiform syllabic script was adopted by many Near

Eastern cultures who adapted it to their different linguistic families and in particular, Semitic (Akkadians and Eblaites); Indo-European (Mitanni, Hittites, and Persians); Caucasian (Hurrians and Urartians); and finally, Elamite (Black, 2008) and Kassite. It is likely that Linear A and B, the phonetic scripts of Crete and mainland Greece, c. 1400–1200 BCE, were also influenced by the Near East.

The Alphabet: The Segmentation of Sounds

The invention of the alphabet about 1500 BCE ushered in the third phase in the evolution of writing in the ancient Near East (Sass, 2005). The first, so-called Proto-Sinaitic or Proto-Canaanite alphabet, which originated in the region of present-day Lebanon, took advantage of the fact that the sounds of any language are few. It consisted of a set of 22 letters, each standing for a single sound of voice, which, combined in countless ways, allowed for an unprecedented flexibility for transcribing speech (Powell, 2009). This earliest alphabet was a complete departure from the previous syllabaries. First, the system was based on acrophony – signs to represent the first letter of the word they stood for – for example, an ox head (*alpu*) was 'a,' a house (*betu*) was 'b' (Figure 6). Second, it was consonantal – dealing only with speech sounds characterized by constriction or closure at one or more points in the breath channel, like b, d, l, m, n, and p. Third, it streamlined the system to 22 signs, instead of several hundreds.

The transition from cuneiform writing to the alphabet in the ancient Near East took place over several centuries. In the seventh century BCE, the Assyrian kings still dictated their edicts to two scribes. The first wrote Akkadian in cuneiform on a clay tablet, and the second Aramaic in a cursive alphabetic script traced on a papyrus scroll. The Phoenician merchants established on the coast of present-day Syria and Lebanon, played an important role in the diffusion of the alphabet. In particular, they brought their consonantal alphabetic system to Greece, perhaps as early as, or even before, 800 BCE. The Greeks perfected the Semitic alphabet by adding letters for vowels – speech sounds in the articulation of which the breath channel is not blocked, like a, e, i, o, u. As a result, the 27-letter Greek alphabet improved the transcription of the spoken word, since all sounds were indicated. For example, words sharing the same consonants like 'bad,' 'bed,' 'bid,' and 'bud,' could be clearly distinguished. The alphabet did not subsequently undergo any fundamental change (Solomon, 2012).

The Modern Alphabets

Because the alphabet was invented only once, all the many alphabets of the world, including Latin, Arabic, Hebrew, Amharic, Brahmani, and Cyrillic, derive from Proto-Sinaitic. The Latin alphabet used in the Western world is the direct descendant of the Etruscan alphabet (Bonfante and Bonfante, 2002). The Etruscans, who occupied the present province of Tuscany in Italy, adopted the Greek alphabet, slightly modifying the shape of letters. In turn, the Etruscan alphabet became that of the Romans, when Rome conquered Etruria in

PROTO-CANAANITE	EARLY LETTER NAMES AND MEANINGS	
	alp	oxhead
	bét	house
	gaml	throwstick
	digg	fish
	hó(?)	man calling
	wó (waw)	mace
	zé(n)	?
	ḥé(t)	fence?
	ṭé(t)	spindle?
	yad	arm
	kapp	palm
	lamd	ox-goad
	mém	water
	naḥš	snake
	cén	eye
	pi't	corner?
	sa(d)	plant
	qu(p)	?
	ra'š	head of man
	tann	composite bow
	tó (taw)	owner's mark

Figure 6 Proto-Sinaitic alphabet (Source: Michael Roaf, 1990. Cultural Atlas of Mesopotamia. Equinox, Oxford, p. 150).

the first century BCE. The alphabet followed the Roman armies. All the nations that fell under the rule of the Roman Empire became literate in the first centuries of our era. This was the case for the Gauls, Angles, Saxons, Franks, and Germans who inhabited present-day France, England, and Germany.

Charlemagne (800 CE) had a profound influence on the development of the Latin script by establishing standards. In particular, a clear and legible minuscule cursive script was devised, from which our modern-day lower case derives. The printing press invented in 1450 dramatically multiplied the dissemination of texts, introducing a new regularity in lettering and layout. The Internet catapults the alphabet into cyberspace, while preserving its integrity.

Writing: Handling Data in Abstraction

Beyond the formal and structural changes undergone by writing in the course of millennia, its evolution also involved strides in the ability to handle data in abstraction. At the first stage, the token system antecedent of writing, already abstracted information in several ways. First, it translated daily-life commodities into arbitrary, often geometric, forms. Second, the counters abstracted the items counted from their context. For example, sheep could be accounted independently of their actual location. Third, the token system separated the data from the knower. That is to say, a group of tokens communicated directly specific information to anyone initiated in the system. This was a significant change for an oral society, where knowledge was transmitted by word of mouth from one individual to another, face to face. Otherwise, the token system represented plurality concretely, in one-to-one correspondence. Three jars of oil were shown by three tokens, as it is in reality. At the same time, the fact that the token system used specific counters to count different items was concrete – it did not abstract the notion of item counted from that of number. (Certain English numerical expressions referring to particular sets, such as twin, triplet, quadruplet and duo, trio or quartet, are comparable to concrete numbers.)

When tokens were impressed on the envelopes to indicate the counters enclosed inside, the resulting markings could no longer be manipulated by hand. In other words, the transmutation of three-dimensional counters into two-dimensional signs constituted a second step in abstraction. By doing away with tokens, the clay tablets marked a third level of abstraction since the impressed markings no longer replicated a set of actual counters. The invention of numerals, which separated the notion of numerosity from that of the item counted, was a crucial fourth step in abstraction. The signs expressing the concept of oneness, twoness, etc. allowed plurality to be dealt with in fully abstract terms. In turn, the phonetic units marked a fifth step of abstraction, since the signs no longer referred to the objects pictured, but rather the sound of the word they evoked.

Phonetics allowed writing to shift from a representational to a conceptual linguistic system. That is to say, it enabled writing to leave the realm of real goods in order to enter the world of words and the ideas they stand for. Finally, the process that started with ideograms expressing concepts and phonetic signs referring to the sound of monosyllabic words reached the ultimate segmentation of meaning with letters. As Marshall McLuhan (Moos, 1997) defined it, the alphabet consists of semantically meaningless letters corresponding to semantically meaningless sounds. The alphabet brought data handling to a final double-stepped abstraction.

Conclusion: The Stability of Writing Systems

The origin of the Chinese script and the development of Mesoamerican writing are still obscure. The Mesopotamian script, however, offers a well-documented evolution over a continuous period of 10 000 years. The system underwent drastic changes in form, gradually transcribed spoken language more accurately, and handled data in more abstract terms. The most striking universal feature of all writing systems, however, is their uncanny endurance, unmatched among human creations. The Chinese script never needed to be deciphered because the signs have changed little during the 3400 years of its recorded existence (Xigui, 2000). It also always remained ideographic, merely inserting rebus-like phonetic complements in some characters. The Mesoamerican Maya phonetic glyphs preserved the symbolism initiated by the Olmecs in the previous millennium (Coe and van Stone, 2005). Finally, when the last clay tablet was written in the Near East, c. 300 CE, the cuneiform script had been in use for three millennia. It replaced an age-old token system that had preceded it for over 5000 years; it was replaced by the alphabet, which we have now used for 3500 years.

Abstract

This article presents evidence-based practices (EBPs) for teaching writing to school-aged students. These practices were drawn from over 20 meta-analyses examining true- and quasi-experiments testing specific writing interventions. The EBPs are presented within the context of two primary theories that have been influential in shaping our understanding of writing and writing development. The social/contextual view of writing emphasizes the importance of context in writing development, including the role of social, cultural, historical, and institutional factors. The cognitive/motivational view stresses the importance of developing students' writing skills, strategies, knowledge, and motivation. Recommendations and caveats for applying the evidence-based writing practices identified here are examined.

In today's world, writing is essential to success. At school, teachers commonly use writing to assess and promote students' learning (National Council of Teachers of English, 2004). At work, white- and blue-collar workers increasingly use writing as part of their job (National Commission on Writing in America's Schools and Colleges, 2004, 2005, 2006). At home, writing is now part of everyday life thanks to e-mailing, blogging, texting, and other forms of digital composing (Hillocks, 2006).

While writing is widely used, there has been a long-standing concern about the quality of writing instruction students receive at school (e.g., Sheils, 1975). This concern has its genesis in two related findings. First, many students do not develop strong writing skills. Even in an affluent country like the United States, only about one-third of students become proficient writers (National Center for Educational Statistics, 2012). Second, little time is devoted to teaching writing in most schools (Applebee and Langer, 2011; Gilbert and Graham, 2010; Kiuhara et al., 2009), and teachers indicate that they are not adequately prepared to teach writing (Brindle, 2012).

This is unfortunate, as writing is an extremely complex skill that is not easily mastered (Graham, 2006a). Good writing depends on the ability to regulate a variety of processes, strategies, and mental operations when planning, drafting, evaluating, and revising text. The creation of well-written text further involves accessing different kinds of knowledge, such as knowledge about the topic, the intended audience, and genre. Writers must apply transcription and translation skills such as handwriting, typing, spelling, and sentence construction to realize their intentions. Because writing is a self-directed task, it also involves engagement and persistence, and it is shaped the writers' motivational state, as attributes such as efficacy, anxiety, and attitudes can enhance or impede its execution. Moreover, writers must intelligently apply these resources across situations, occasions, and contexts over time.

One approach for addressing the quality gap in writing instruction in schools is through the use of evidence-based practices (EBPs; Cook et al., 2012). These are "instructional approaches shown through high-quality research to result in generally improved student outcomes" (Cook et al., 2012: p. 495). This is the approach adopted here, as I draw on 21 past meta-analyses of writing interventions studies employing true or quasi-experimental designs (Andrews et al., 2006; Bangert-Drowns, 1993; Bangert-Drowns et al., 2004; Gersten and Baker, 2001; Goldberg et al., 2003; Gillespie and Graham, 2014; Graham, 2006b; Graham et al., 2012a; Graham and Harris, 2003; Graham et al., 2011, 2013b; Graham and Hebert, 2011; Graham et al., 2012b; Graham and Perin, 2007a,b; Graham and Santangelo, 2014; Graham et al., in press; Hillocks, 1986; Morphy and Graham, 2012; Sandmel and Graham, 2011, 2013) to identify EBPs for writing. In true-experiments, students are randomly assigned to the writing treatment and control condition. Such randomization does not occur in quasi-experiments.

With meta-analysis the magnitude and the direction (positive or negative) of the effects of a writing practice are averaged across all pertinent studies. I share here writing EBPs that resulted in positive and statistically significant effects in improving the quality of students' writing across studies testing a specific writing intervention. We present these EBPs within the context of a view of writing development that emphasizes both the social/contextual as well as cognitive/motivational aspects of writing (Graham et al., in press).

Writing Development

Our understanding of how writing develops is incomplete, but enough is known to be certain that the road to competence depends on the context in which writing takes place as well as what the writer brings to the task cognitively and motivationally (Graham, 2006b). The work of Russell (1997) aptly illustrates the social/contextual view of writing development. He emphasizes the importance of two structures in his model of writing. One is *activity system*, which specifies how actors (a student, pair of students, student and teacher, or class perceived in social terms and taking into account the history of their involvement in the activity system) use concrete tools, such as paper and pencil or word processing, to accomplish an action leading to an outcome. For instance, a desired outcome, such as the collaborative creation of a text explaining the idea of balance, is

accomplished in a problem space where the actors use writing tools in an ongoing interaction with others (peers and teachers) to shape the text that is being produced over time in a shared direction.

The second structure in Russell's (1997) model is *genre*: a "typified way of purposefully interacting in and among some activity system(s)" (p. 513). These genres become stabilized via regularized use by and among students, creating a predictable approach for writing within a classroom (e.g., plan, draft, revise, edit, and publish). Genres are conceived as temporarily stabilized structures, however, because they are subject to change depending on the context. For example, a new student entering a classroom with established and stabilized genes (e.g., Edit before publishing your paper) will likely appropriate some of the routinized practices of his classmates. The youngster may, in turn, create changes in existing genres by applying writing routines learned at his old school (e.g., Get feedback on your writing plan before editing) and deemed as valuable by his new teacher, classmates, or both.

In contrast to the social/contextual view of writing, the cognitive/motivational approach concentrates primarily on the individual writer and the mental and affective processes involved in composing text, as illustrated in a model of skilled writing developed by Hayes (1996). He identified the mental moves, cognitive processes, and motivational resources writers draw on as they write. This includes mental processes such as text interpretation, reflection, and text production that writers use to create a representation of the writing task; develop a plan to complete it; draw conclusions about the audience and possible writing content; use cues from the writing plan or text produced so far to retrieve needed information from memory; turn these ideas and information into written sentences; and evaluate plans and text and modify them as needed. It also includes long-term memory which contains a variety of resources, such as topic knowledge and schemas, for carrying out particular writing tasks, as well as working memory which serves as a temporary place for holding ideas for writing and carrying out mental operations that require the writer's conscious attention. The application of these mental operations and cognitive processes is influenced by a variety of motivational factors, as writers' goals, predispositions, beliefs, and attitudes shape what they do.

Together, the social/contextual and cognitive/motivational viewpoints provide needed structure for designing an effective writing program. One, it is important to create a writing context that is supportive. This includes developing classroom routines that make writing an interesting and enjoyable activity as well as using instructional procedures and writing tools that support students as they write. Two, it is equally important to make sure students acquire the skills, strategies, and knowledge they need to become skilled writers. EBPs for obtaining these goals (based on the meta-analyses referenced earlier), including the use of writing as a tool for learning, are presented next.

Create a Supportive Writing Context

As students develop as writers, they learn to write for many purposes (e.g., entertain, persuade, learn, inform, communicate), while composing in a planful, thoughtful, reflective, and collaborative manner, through the use of multiple technologies (e.g., pen and paper, word processing) and modalities (written text combined with visual and auditory material). Such applications of writing are not only demanding mentally, but require learning and working with others in a productive manner. This makes it especially important to develop a writing environment where teachers support students and their writing efforts and students support each other in a positive and motivating manner.

One EBP, the process approach to writing (see Sandmel and Graham, 2011), includes a number of mechanisms for creating a supportive writing context. This includes creating a pleasant and positive writing environment; writing for real audiences and authentic purposes; creating routines that emphasize what students need to do as they write (i.e., plan, draft, evaluate, revise, and edit); stressing personal responsibility and ownership of writing projects; encouraging self-reflection and evaluation; promoting high levels of student interactions to support writing; and providing students with personalized individual assistance and feedback, as well as brief instructional lessons, as needed.

This general approach to creating a supportive writing environment can be complemented by the application of other more specific EBPs, some of which are instantiations of the practices included in the process approach to writing. One, students' writing can be strengthened by creating routines that ensure they write frequently (e.g., Graham et al., 2012b). The basic premise underlying this EBP is that students must write frequently if they are to prosper and grow as writers. This allows developing writers to become comfortable with writing and further hone their writing skills.

Two, students are likely to produce better text when the goals for their writing are clearly established (e.g., Graham et al., 2012a). Goals work best when they are clear, specific, and reasonably challenging. For instance, an appropriate goal for 10 to 12-year-old students might include: addressing both sides of an argument, providing three or more reasons to support your point of view and countering at least two reasons supporting the opposing view when writing an argument.

Three, developing a supportive writing environment requires some consideration of the tools students use to compose. Many schools just use pencil and paper as the writing medium, instead of more modern writing tools, such as a word processor and other digital writing tools which may make it possible to compose through multiple modalities. These tools have many advantages over paper and pencil (e.g., Bangert-Drowns, 1993; Morphy and Graham, 2012). For instance, electronic text produced via word processing is legible, and it can easily be deleted, added, rewritten, or moved. Other software which support writers, such as spell checkers or speech synthesis, may be included as part of this writing tool. Word processor can be connected to the Internet and other programs where students can gather material for what they write, as well as share their text with others.

Four, writing development can also be facilitated by having students work together as they compose (e.g., Graham and Perin, 2007b). This includes working together to plan, draft, revise, and edit their compositions. A common characteristic of studies that tested this collaborative approach was that students were provided with specific directions for what to do when working together and then taught how to carry out these

procedures. To illustrate, in one study (Yarrow and Topping, 2001), teachers applied a systematic instructional routine (i.e., exploration, demonstration, clarification, practice, monitoring, coaching, and reinforcement) to teach students how to successfully work with a peer as they planned, drafted, revised, and edited their papers.

Five, students' writing development can be enhanced through formative assessment practices (Graham et al., 2011). When teachers monitor students' progress as writers, they can adjust classroom practices to meet the collective as well as the individual needs of their students. When students evaluate their own writing, writing improves. When students receive feedback about their writing, writing improves. When students are partners in writing assessment, giving and receiving peer feedback, students' writing improves.

Help Developing Writers Acquire Needed Skills, Knowledge, and Strategies

Skilled writing requires mastery or facility with a wide range of skills (e.g., handwriting, typing, spelling, grammar, and usage), knowledge (e.g., attributes of specific types of text such as persuasive, informative, and narrative), and strategies (e.g., planning, drafting, revising, and editing text). How can developing writers acquire competence in these areas? It is clear, based on the accumulated evidence from the available meta-analyses, that explicitly teaching writing skills, knowledge, and strategies is advantageous, as such instruction makes students better writers (Hillocks, 1986; Graham et al., 2012b; Graham and Perin, 2007b). While most of the EBPs presented next involve explicit instruction, it is important to keep in mind that students also acquire skills, knowledge, and skills through less direct practices too. For example, students learn much of what they need to know about spelling as a result of reading and writing (Graham, 2000). The challenge is to know what combination of explicit and implicit instructional practices should be applied when?

Teach Foundational Writing Skills to Beginning Writers

Skilled writers rarely think about handwriting, typing, or spelling when they compose. These skills are executed correctly and with little or no conscious attention. Such mastery is important, as having to devote conscious attention to these skills can interfere with other writing processes (Scardamalia and Bereiter, 1986). Explicitly teaching such skills to elementary grade students improves the overall quality of their writing (Graham et al., in press), with the added bonus that teaching spelling improves students' reading skills too (Graham and Santangelo, 2014).

Writers invest considerable energy into transforming their ideas into the words and syntactic structures that convey their intended meanings. This includes constructing sentences as well as using appropriate grammar, punctuation, capitalization, and so forth. An EBP for improving such skills is sentence-combining (Andrews et al., 2006; Hillocks, 1986). This involves the teacher modeling how to combine two or more sentences into a more complex one, followed by student practice combining similar types of sentences.

Increase Developing Writers' Knowledge for and about Writing

Three types of knowledge that developing writers need to acquire are knowledge about their writing topic, knowledge about genre, and knowledge about the words they use to convey meaning (Olinghouse et al., 2012; Olinghouse and Wilson, 2013). An EBP for addressing the issue of content knowledge is for teachers to put into place practices that help students gather ideas and information to write about (e.g., Graham and Perin, 2007a). Examples of such activities include locating possible writing content through brainstorming, reading, drawing, the Internet, and/or by using graphic organizers.

An EBP for acquiring genre knowledge is to teach students about the basic characteristics of specific types of text (Graham et al., 2012b). For example, teachers and students might read a series of stories together in order to define and identify the basic elements (e.g., setting, episode) included in such narratives. A second EBP for acquiring genre knowledge is to provide students with model text for a specific type of writing and ask them to emulate it (e.g., Hillocks, 1986).

Although not as well studied as most other EBPs, teaching students specialized vocabulary to use in their writing can improve what students' write (Graham et al., in press). For example, teaching students words about outer space can improve what they write about this topic. When writers use such vocabulary correctly in their compositions, they show their understanding of the topic and express their ideas in a way that is likely to be valued and accepted by their readers, including their teacher (Olinghouse and Wilson, 2013).

Teach Developing Writers Strategies for Planning, Drafting, Revising, and Editing

Skilled writers use strategies for planning, drafting, revising, and editing to help them create and improve what they write (Zimmerman and Reisemberg, 1997). These strategies range from more general strategies such as brainstorming, semantic Webbing, or editing which can be applied across genres to strategies that are designed for specific types of writing. For instance, when writing a story, the writer may generate possible ideas for writing by thinking about the characters, the setting, the main character's goals, action to achieve those goals, characters' reactions, and how the story ends (see Graham and Harris, 2005; Harris et al., 2008 for other examples).

When developing writers are taught strategies for planning, drafting, revising, and editing the overall quality of their text improves (Graham et al., 2012b). Strategy instruction involves teachers explaining the purpose and rationale of the strategy, modeling how to use it, and providing students with assistance in applying the strategy with the goal of independent and effective application. Such instruction is improved, however, when students are also taught the knowledge or skills they need to effectively use the target writing strategy, made aware of the

gains that result through its use, attribute these gains to effort and strategy use, and set goals to learn and apply the new strategy (see Harris et al., 2008).

Use Writing to Support Students' Reading and Learning

Writing about material read, presented in class, or obtained through other means may be advantageous for multiple reasons (Graham and Hebert, 2011). Writing about such material requires that the writer decides what ideas are most important and how they are related one to another. The permanence of writing makes it possible for the writer to review, reexamine, critique, and even construct new understandings of the extracted material. When writers put these ideas into their own written language it can make them think more carefully about what the ideas mean.

The available evidence indicates that when students write about material they are learning in class their learning increases (Bangert-Drowns et al., 2004; Graham and Perin, 2007b). Likewise, writing about material read enhances students' understanding and retention of such material (Graham and Hebert, 2011). This was true across disciplines as varied as the language arts, science, social studies, and mathematics. Example of writing activities that promoted student learning included writing short answers to questions, taking notes, writing a summary, and writing more extended responses such as explaining how something learned can be applied or relates to one's own life.

Students with Special Writing Needs

Learning to write can represent a major challenge for students with a disability, as many of these youngsters write well below grade level (National Center for Educational Statistics, 2012). While we know less about how to teach writing effectively to students with disabilities than to their classmates without disabilities, enough writing intervention research has been conducted with students with learning disabilities that five EBPs have been identified (Gersten and Baker, 2001; Gillespie and Graham, 2014; Graham et al., in press; Morphy and Graham, 2012).

Four of the five identified EBPs for students with learning disabilities were also EBPs for developing writers in general. These included implementing a process approach for writing instruction; establishing specific, challenging, but realistic goals for students' writing; teaching strategies for planning, drafting, revising, and using word processing as the primary medium for composing. This last EBP was especially effective when other software, which provided support for planning and revising was included as part of the program. Such word-processing programs are less likely to be effective, however, if students' typing skills are slow (MacArthur and Graham, 1987).

The fifth EBP for students with learning disabilities was dictation. This primarily involved students dictating some part of their composition (e.g., plan, draft) into a tape recorder, which was later transcribed by the student or someone else. There are obvious limitations to dictation, especially when someone else must transcribe it, which limits its implementation. Speech-to-text synthesis word-processing programs provide a workable alternative, but they do not yet provide fully accurate transcription, especially for younger developing writers.

Collectively, the intervention research conducted with students with learning disabilities demonstrates that teachers can improve the writing of students who experience considerable difficulty with writing and learning. It is imperative that these students, and all other students for that matter, receive the best writing instruction available in order to maximize their writing growth.

Caveats

This article provides guidance on possible writing practices and interventions that teachers can apply to help students become better writers. It draws on scientific testing of writing interventions through true- and quasi-experiments to identify EBPs that improve the quality of students' writing across multiple studies. The advantage of such an approach is that it provides a relatively trustworthy method for identifying effective teaching practices in writing, as such studies provide evidence on whether the instructional procedure produced the desired impact, the observed effects are representative, and how much confidence can be placed in them (Graham, 2010).

It must be noted, however, that there are other sources of evidence for identifying effective practices for developing writers. These include the practices applied by highly effective teachers as well as practices identified through other forms of research, such as single subject design studies (Horner et al., 2005). These various forms of evidence are not incompatible with one another, and many of the EBPs presented here are commonly used by highly effective teachers (Graham and Perin, 2007c) and identified as effective using single subject research methodology (Rogers and Graham, 2008).

One challenge in implementing writing EBPs into everyday classroom practices involves teacher preparation. Many teachers, but especially content area teachers, indicate that their preparation to teach writing is inadequate (e.g., Kiuhara et al., 2009). If the EBPs identified here are to become a positive and routine aspect of classroom life, then the professional development teachers receive in college, through their schools or school district, from their profession, and through their own efforts must provide them with the knowledge and skills needed to implement them effectively.

A second challenge in implementing the practices identified here is that we do not know what combination of writing EBPs is most effective. This is likely to depend on a variety of factors including who the students are, where they are at in their development, the setting in which instruction takes place, and the expertise of the teacher. This challenge should not be underestimated, as a student's writing development is uneven across different types of writing (Graham et al., 2011), and students likely benefit from different forms of support at different points in their development.

A third challenge to implementing writing EBPs revolves around the different organizational structures or formats for writing that exist in schools today. Writing instruction can occur within the context of the language arts classroom, a content area

classroom, or with a learning specialist, such as a special education teacher. These options are not exclusive, however, as they can be combined in various ways. For example, a language arts and a learning specialist might use subject matter, such as science or social studies, as a focal point for writing instruction. To illustrate, they might collaborate in teaching strategies for planning and writing persuasive essays using text students read in a concurrent social studies class. Furthermore, a social studies teacher and the language arts instructors could align their curricula, giving students assignments that systematically connect writing and content instruction. To illustrate, in a study by De La Paz (2005), a history teacher taught a historical reasoning strategy using historical documents, and the language arts teacher taught strategies for writing argumentation essays, using the documents applied by the history teacher.

The effectiveness of such various formats has neither been tested or compared one to another, so it is not certain how well the EBPs identified here would fair in these different formats. Before implementing a writing EBP, a careful analysis of the organizational structure or format within which it well be placed should be undertaken, with the aim of identifying factors that will facilitate and impede their effectiveness.

While research investigating writing instruction spans more than 100 years of study, it must be noted that there are many gaps in our knowledge about how to teach writing effectively. Some writing practices have not been scientifically tested at all and others have been tested sparingly. Over time, other effective writing practices and interventions will be identified. Thus, the EBPs presented here provide a starting point, not an end point, for developing effective programs for developing writers.

It should further be recognized that our knowledge about teaching writing effectively to all students is incomplete. For example, very little writing intervention research has been conducted with students learning to write in a second language. In fact, virtually none of the research included in the meta-analyses that formed the basis for the EBPs presented here was conducted with these developing writers. This is also the case for very young writers (3–5 years old) and students with disabilities other than learning disabilities. Likewise, we know much less about teaching writing to struggling writers than typically developing ones.

Finally, the use of writing EBPs likely hold their greatest promise for helping teachers and schools develop students who are skilled and confident writers if they are implemented as part of a comprehensive reform of writing instruction. To address the long-standing concerns about students' writing and the neglect of writing instruction in many classrooms, policy makers and the educational community need to develop new and better policies that establish unambiguous, challenging, and realistic plans for improving writing instruction and students' writing. These plans should specify methods and incentives to ensure that teachers are prepared to teach writing effectively; the teaching of writing is the responsibility of all teachers; students write frequently; students use writing as a tool to support learning across the curriculum; sufficient time is devoted to teaching of writing at all grades; and students increasingly use twenty-first century digital writing tools.

We encourage teachers to learn more about the writing EBPs presented here before applying them, and to use each practice judiciously with good common sense. Teachers should monitor the success of these practices as they apply them and make needed adjustments accordingly. Just because an intervention was effective in multiple research studies does not guarantee that it will be effective in all other situations. There is rarely, if ever, an exact match between the conditions in which the intervention was tested, and the conditions in which it is subsequently implemented by teachers. The safest course of action, therefore, is for teachers to monitor if the applied practices are working in her or his classroom.

Writing Systems

Roger D Woodard, The University of Buffalo, Buffalo, NY, USA

Abstract

Writing systems, means of graphically recording language, are of three fundamental types: (1) *logographic systems* which consist of nonphonetic symbols, called *logograms*, which represent entire words; (2) *syllabic*; and (3) *segmental* writing systems which comprise *phonetic* symbols representing syllable-units and individual sounds, respectively. Segmental scripts can be further divided into two types: those representing only consonants (*alephbeths*) and those spelling both consonants and vowels (*alphabets*). Writing first appears among the Sumerians of southern Mesopotamia in the late fourth millennium BC and reveals itself in Egypt not long thereafter. Both the Sumerian and Egyptian systems are partially logographic and partially phonetic (the former syllabic, the latter segmental). The first attested script that consists solely of symbols for individual sounds (consonants) is called *Proto-Sinaitic*, used to write the Canaanite language of a people living in Egypt early in the second millennium BC. Proto-Sinaitic is one form of the more widely attested *Proto-Canaanite* script, ancestor of the Phoenician alephbeth, which is itself the source of the Greek alphabet, appearing in *c*.late ninth/early eighth century BC (the Greeks had earlier written with the syllabic scripts called *Linear B* and the *Cypriot Syllabary*). The Phoenician script is also the source of the Aramaic writing system, which in turn probably gave rise to the early scripts of India. Writing appears independently in China by *c*.1200 BC. Chinese writing is parent to Japanese (by the end of the ninth century AD); early Korean was written with Chinese characters, but the native Han'gul appeared in perhaps the fifteenth century AD. Writing also develops independently in Mesoamerica, as among the Maya by at least the third century AD.

The term 'writing system' specifically denotes a set of symbols that is used for the graphic (written) recording of language. Its use is commonly synonymous with that of the term 'script,' and the two are used interchangeably; however, the notion 'writing system' may additionally include the conventions (or spelling practices) which dictate how the symbols of such a system can be used. Forms of graphic expression which may have some semantic content – such as cave drawings, petroglyphs, icons, and even sophisticated picture messages – but which do not or could not record a linguistic utterance directly, are thus excluded from the realm of *writing*. This is not to suggest that all writing systems are capable of recording language with equal precision, but that by definition writing systems are fundamentally linguistic.

Types of Writing System

Writing systems are of three fundamental types. Logographic systems consist of symbols, called logograms, which represent entire words. In opposition to the two remaining types, a logographic system is said to be non-phonetic to the extent that its minimal elements record the pronunciation of an entire word, rather than representing the individual phonetic components (consonants and vowels) that make up the word. The reality of the phonetic opacity of such a system becomes obvious when one works with an ancient language recorded with logograms. It may be possible to identify the meaning of a logogram by its context and other clues, but if the word which it represents is not also attested by a more revealing, phonetic writing system, its pronunciation will remain uncertain or unknown.

In contrast to logographic scripts, syllabic, and segmental writing systems are said to be phonetic. A syllabic system consists of symbols, syllabograms, which have the value of a single syllable (although the syllables of a word spelled with a syllabic script may not actually line up with the syllabograms used in a one-to-one fashion). Syllabaries most commonly possess symbols of the value V (vowel) and CV (consonant + vowel); CCV, CVC, VC, among still other permutations, also occur, though less frequently.

Segmental writing systems are those which are composed of symbols representing individual sounds and are themselves of two types. Consonantal scripts (or alephbeths) have symbols for consonants only. Alphabets are characterized by both consonant and vowel symbols.

The relationship of the three types of writing systems to one another is in large measure of a historical, developmental nature. Consequently, the ensuing discussion will roughly follow a chronological scheme. As will be seen, most writing systems are not purely logographic or phonetic, but display some degree of hybridization.

The Birth of Writing

On the basis of presently available evidence, it appears that human beings first began to record language in southwest Asia and northeast Africa. Until quite recently, the very earliest examples of writing were held to be found among the archaeological remains of ancient Mesopotamia. However, a recent hypothesis would place the appearance of writing in Egypt at approximately the same time as its first attestations in Mesopotamia.

Mesopotamian Writing

Writing appears among the Sumerians of southern Mesopotamia in the late fourth millennium BC, and it is the Sumerians who are commonly credited with the invention of writing, although it appears to be attested not much later in Syria (at Tell Brak) and in Iran (in texts preserving the poorly

understood language of Proto-Elamite). The events which led to the advent of Sumerian writing are of course unknown, although there are various theories regarding its appearance. In the view of some scholars, the Sumerian invention of writing was a deliberate act, probably occasioned by the needs of palace administrators, and most likely in the city of Uruk where it is first attested. Others would see the process as being more of an evolutionary, in effect accidental, nature.

Regardless of the nature of the crucial step which led to the appearance of a system of writing on the Sumerian Plain, it seems undeniable that a precursor of the script is to be found in the clay tokens which had been in use for record keeping in Mesopotamia since at least 8000 BC. Some of these tokens actually resemble the commodity that they depict; others are of an arbitrary shape. By the latter half of the fourth millennium BC, some tokens had begun to be used as stamps, being impressed into moist clay tablets to produce administrative ledgers. Other tokens, those of more complex design, began to be etched freehand in the clay using a stylus. Schmandt-Besserat (1996) has argued that the appearance of Sumerian logographic writing was a natural evolutionary step following from the practice of inscribing token images (a process linked, she argues, to the development of symbols for abstract numerals).

As suggested by their conjectured association with tokens, the earliest Sumerian symbols are *pictographic*; in other words, the symbols have a picture-like appearance. The curved lines of the pictographic characters began, however, to give way to more angular, conventionalized shapes. Such conventionalization of symbols is a common process in the evolution of writing systems, but in this instance that process and the direction of development were dictated by the medium and instruments of writing. The chief medium used throughout the history of Sumerian writing was clay. Sumerian scribes first incised their pictographic characters in wet clay tablets using pointed styli. These, however, were replaced by a stylus with a triangular-shaped head that was simply pressed down into the clay, allowing for more rapid and efficient production of the symbols. Characters produced in this way have a characteristic wedge shape (quite pronounced by the middle of the third millennium BC), and are hence called cuneiform (from the Latin *cuneus*, 'wedge').

The value of early Sumerian symbols is logographic: each symbol represents an entire word. This logographic system is characterized by extensive homophony and polyphony. Homophony refers to the existence of multiple logograms having the same pronunciation, as they spell phonetically identical but semantically different words (homophones). Polyphony is, in a sense, the very opposite; the term denotes the practice of using a single logogram to spell two or more conceptually related but phonetically different words. For example, a single logogram is used to spell both DINGIR 'god' and AN 'heaven' (by Sumerological convention, Sumerian words are transcribed using capital letters).

A subset of the Sumerian logograms did double duty as semantic markers, called determinatives. These were written in conjunction with another logogram and were used, in effect, to provide the reader with a clue as to the meaning of that logogram, although their use is both conventionalized and optional. For example, the logogram GIŠ, 'wood,' is used as a determinative with logograms denoting items made of wood and tree names, such as ^{giš}ERIN, 'cedar' (determinatives are commonly transcribed as superscript). Similar devices also occur in the logographic Egyptian and Maya scripts, and in a somewhat different form in Chinese writing as well.

Sumerian is an agglutinating language with complex word structure involving the joining of multiple affixes in sequence. Logographic spelling thus obscures much word-internal morphology. Perhaps, it was chiefly this inherent shortcoming that led to a significant typological alteration in the Sumerian logographic writing system – the introduction of syllabic symbols (by about 3000 BC). The method employed in devising such symbols was that of a rebus. Just as in an English rebus, a picture of the sun, for example, could be used to 'spell' the word 'son,' so Sumerian logograms began to be used to represent syllables having the same sound. Sumerian scribes used the syllabic symbols not only for representing grammatical elements but also as phonetic complements, syllabic characters used to distinguish between polyphonous logograms. For example, the logogram KA was used to spell 'mouth' as well as related notions such as 'word,' 'speak,' and 'voice'; attaching the phonetic complement *-ma* (i.e., KA-*ma*) signals that the logogram is being used to spell INIM 'word.'

Late in the third millennium BC, texts begin to appear in the Mesopotamian archaeological world that are written in the cuneiform script of the Sumerians, but which are composed in a completely different language, the Semitic language of Akkadian. The Assyrians and Babylonians, speakers of Akkadian, greatly extended the use of syllabic symbols, but continued to utilize Sumerian logograms and determinatives as well. The Akkadian cuneiform script was transmitted to other peoples of the Near East, providing writing systems for the Hittites and Luvians, the Hurrians and Urartians, the Elamites, and, in a significantly streamlined form, the Persians. The latest known Akkadian cuneiform texts were produced in the first century AD.

Egyptian Writing

While the pictographic symbols of the Egyptian hieroglyphic script are clearly graphically distinct from those of Sumerian, and the internal operation of the two scripts shows appreciable differences, similarities are undeniable. Both possess a logographic component; both have a phonetic component, which is commonly used for phonetic complementation; both expand the use of symbols through the rebus principle; both use a subset of logograms as determinatives. As it has appeared that the Egyptian script is first attested a bit later than the Sumerian (about 3100–3000 BC), as there is evidence for a precursor to the Sumerian logograms, and as Egypt was otherwise being influenced by Mesopotamia at the end of the fourth millennium BC, it has been commonly conjectured that at least the idea of writing, if not a writing system itself, came to the Egyptians from Mesopotamia. One possible difficulty with this scenario is that the Egyptian writing system appears well developed at its earliest attestation, perhaps suggesting some earlier, undocumented period of use.

From the Abydos tomb complex in Upper Egypt, small ('postage-stamp-size') tags of bone and ivory have been recovered on which are carved symbols that in some cases bear

similarity to later-known hieroglyphs. Günter Dreyer (1998) has dated these tags to around 3400–3200 BC and interpreted the symbols as writing. The dating of the tags and, perhaps more crucially, the interpretation of their markings continues to be explored.

The most striking difference between the Egyptian and Sumerian systems is the nature of the phonetic component. In Egyptian writing the phonetic symbols do not have syllabic value, but represent consonants – either single consonants or sequences (although not necessarily phonetically contiguous strings) of two or three consonants. Twenty-six monoconsonantal symbols occur (including two variant forms), representing the individual consonants of the language; there are almost 100 biconsonantal symbols, and somewhat fewer triconsonantal. Biconsonantal and triconsonantal phonetic symbols are often themselves accompanied by one or more monoconsonantal phonetic complements. For example, the triconsonantal symbol *nfr*, spelling the Egyptian word meaning 'good,' is commonly used in conjunction with one or two monoconsonantal complements, as in the spelling sequence *nfr f r*.

Consonantal Writing Systems

During the early second millennium BC, a Semitic people living and laboring in Egypt developed a script for their own language by exploiting a single component of the Egyptian writing system. With the inspiration provided by the monoconsonantal Egyptian symbols, these people designed a fully phonetic and greatly simplified writing system which consists entirely of symbols for individual consonants. The first evidence of the script, labeled Proto-Sinaitic, came to light in the early twentieth century with Sir Flinders Petrie's excavations of Egyptian turquoise mines at Serabit el-Khadim in the Sinai; hence the name. Quite recently, additional examples of Proto-Sinaitic writing have been discovered near the ancient city of Thebes, along the Farshût Road at Wadi el-Hol, dating *c.* 1850 BC (Darnell et al., 2005). The evidence from Wadi el-Hol suggests that development of the script was significantly motivated by written-communication needs among Semitic-speaking mercenaries serving in the Egyptian army.

The method that the adapters employed in turning the Egyptian script to their own use was dubbed the acrophonic principle by the British Egyptologist Sir Alan Gardiner. The values assigned to the phonetic characters of this earliest Semitic script – characters of pictographic form – were determined by the initial consonant of the Semitic word for the symbol depicted, rather than by any phonetic value associated with a corresponding Egyptian symbol. For example, the Egyptian hieroglyphic symbol resembling waves of water and used in the Egyptian system as a monoconsonantal symbol with the value /n/was assigned the value /m/ in the Proto-Sinaitic script, as the word for 'water' in the West Semitic language of that script began with /m/. The Proto-Sinaitic character for /n/, on the other hand, was based on the Egyptian symbol representing /dž/, a hieroglyph depicting a serpent, and received its Proto-Sinaitic value from the initial consonant in the Semitic word for 'snake.'

Proto-Sinaitic is one particular form (the earliest by the interpretation of an origin within Egypt) of a more broadly, if meagerly, attested consonantal script called Proto-Canaanite, found at several sites in Syria–Palestine. This Proto-Canaanite script is the immediate ancestor of the Phoenician script (appearing in the eleventh century BC), which is in turn the source of the ancient Hebrew (*c.*ninth century) and Aramaic (*c.*eighth century) writing systems (the Hebrew language began to be written with the Aramaic script during the sixth century BC, although the Samaritan sect continued to use the old Hebrew letters). The Aramaic script gave rise to the writing system of Syriac (*c.*first century AD, and late enough to be influenced by the Greek alphabet) and, through the particular Aramaic script used by the Arab Nabateans, to the Arabic writing system (*c.*fourth century AD).

Proto-Canaanite writing also served as the inspiration and model for the script of the ancient Levantine city of Ugarit. The Ugaritic writing system, however, departs markedly from the other Canaanite scripts in that its symbols are of cuneiform shape. It thus represents something of a hybrid writing system, combining the consonantal nature of Proto-Canaanite with the graphic form of the Mesopotamian scripts, although some scholars have argued that the shapes of the Ugaritic consonantal characters were themselves modeled on the Proto-Canaanite symbols but executed with the cuneiform stylus. The Ugaritic writing system also differs from other Canaanite scripts to the extent that it does not consist wholly of consonantal characters, but includes in its graphemic inventory three CV syllabic symbols, representing a glottal stop followed by the vowels /a/, /i/, and /u/.

Yet a different Semitic writing tradition would descend from the Proto-Canaanite script. In the south of the Arabian peninsula a distinct consonantal script had appeared by at least the sixth century BC, and certainly had begun to develop several hundred years earlier. An interesting feature of this Old South Arabian script is that the order of its letters departs from that of Phoenician and the consonantal script of Ugarit. However, an abecedary found at the Palestinian site of Beth Shemesh, consisting of consonantal cuneiform characters like those in use at Ugarit, shows the same letter order as found in the Old South Arabian script. The consonantal script of South Arabia spread northward to be adapted for use by early North Arabian languages (distinct from Arabic) and westward to the horn of Africa, where it was employed for writing the Semitic language of Ethiopic. Interestingly, the consonantal script of Ethiopic had undergone a significant metamorphosis by the fifth century AD, becoming a syllabary of almost 200 CV symbols.

Mediterranean Syllabaries

Crete

In roughly the same period that a Semitic people resident in Egypt were fashioning a consonantal script out of Egyptian hieroglyphs, three writing systems were emerging among the Minoans of Crete. Probably the first to appear was the pictographic script called Cretan Hieroglyphic. Dating back to about the eighteenth century BC is a second Minoan script, attested on only a single document, the Phaistos Disk. A third script, also appearing in the eighteenth century and likely to be descended from Cretan Hieroglyphic, is the one that was labeled Linear A by Sir Arthur Evans, the British archaeologist

who excavated the Minoan city of Knossos early in the twentieth century. The name reflects the linear nature of this script's symbols in contrast to the pictographic quality of symbols in the other two Minoan scripts. None of these ancient Minoan scripts has yet been deciphered by modern investigators, although recent work on Linear A may suggest that it records an Indo–European language of the Anatolian subfamily (an idea first proposed in the mid-twentieth century by the British classicist and linguist L.R. Palmer). Cretan Hieroglyphic is possibly a syllabic script, as is probably that of the Phaistos Disk; Linear A is certainly a syllabary.

In his excavations at Knossos, Evans unearthed documents written in yet a different script, but one that bears an unmistakable similarity to Linear A: this writing system was accordingly given the name Linear B. In the early 1950s the Linear B script was successfully deciphered by Michael Ventris, a British architect, working in collaboration with the Cambridge classicist John Chadwick. The language of the Linear B documents turned out to be Greek – that dialect used by the Mycenaean Greek culture of the second-half of the second millennium BC. The identification of the language of the Linear B script was made particularly difficult by the seeming unsuitability of the script for spelling that language. The great majority of the symbols of this syllabic writing system are of the type CV. As Greek has many word-internal CC sequences and word-final consonants, spelling practices were devised which in some cases required the use of CV symbols for spelling consonants only (with no following vowel), and in some cases resulted in a consonant not being spelled at all. The basic strategy for spelling consonant sequences is one that co-opts a phonological property of the Greek language, namely the relative sonority of consonants. It is the general case that a consonant is written when it precedes a consonant of greater sonority (such as a stop occurring before a fricative), utilizing the CV symbol whose vocalic component is identical with the vowel which follows the consonant sequence, but is not written if the ensuing consonant is of less sonority (such as a fricative before a stop). In either case, the second consonant is written (with the appropriate CV symbol). Word-final consonants are not written and this practice appears to be a further expression of the sonority-based strategy.

Cyprus

There is evidence for writing on the eastern Mediterranean island of Cyprus as early as the middle of the second millennium BC. The writing system in use in that period is preserved in distinct forms called Archaic Cypro-Minoan and Cypro-Minoan I, II, and III (although the last type is actually attested in the documentary remains of the city of Ugarit, on the neighboring Levantine coast, and not on Cyprus itself). In spite of the fact that none of the three has yet been deciphered, the formal similarities between these scripts and those of Minoan Crete suggest that the Bronze Age Cypriot writing system had its origin in the Cretan scripts.

Cyprus was a key locale lying along the trade routes which stretched from Greece to the east, and certainly for this reason there had been a Greek presence in Cyprus during the Mycenaean era; however, the Greek population of Cyprus increased dramatically as refugees fled the conflagration which brought an end to the Mycenaean civilization in the Greek homeland. The earliest remains of Greek writing in Cyprus come from the middle of the eleventh century BC, and the system of writing used was that of the Cypriot Syllabary. This syllabary, while probably based graphically upon Cypro-Minoan I is clearly closely affiliated with the Mycenaean script. Like Linear B, the Cypriot Syllabary is composed predominantly of symbols having the value CV. The same problems of representing word-internal consonant sequences and word-final consonants which Linear B scribes faced also plague the Cypriot Greek writing system; and the Cypriot solutions to these problems are virtually identical to those utilized by the Mycenaeans, being based upon the relative sonority of Greek consonants. The notable difference between the two systems in this regard is that the Cypriot writing system makes much more limited use of the CV-deletion strategy than does Linear B. In most instances in which the first of two consonants is of greater sonority, the Cypriot strategy is to write that consonant (and not to refrain from writing it, as in Linear B) using a CV symbol whose vocalic component is identical to the vowel that precedes the consonant sequence.

The Alphabet

The Greek Origin

It was the Greeks who created the first segmental writing system designed to represent not only consonants but vowels as well. The raw material for the Greek alphabet was provided by the consonantal script of the Phoenicians. As there was both a significant Phoenician presence on the island of Cyprus and a vibrant tradition of Greek literacy, Cyprus provides a *de facto* likely candidate for the cultural center that played a crucial role in the creation of the Greek alphabet, an event that likely occurred in the early eighth or late ninth century BC. There are, moreover, particular features of the early Greek alphabet which are not motivated within that segmental script, but which are motivated within the Cypriot Syllabary. For example, the biconsonantal symbol *xi*, representing the sequence of /k/ +/s/, is unnecessary within a segmental script that has both a *k*-symbol (*kappa*) and an *s*-symbol (*sigma*). Within the Cypriot Syllabary, however, *ks*V symbols are idiosyncratically required by the strategy of consonant cluster spelling which is based upon the relative sonority of consonants, co-incident to Greek phonological structure (Woodard, 1997b). Cypriot Greeks appear to have transferred this and other systemic features from their operationally complex syllabic script to the newly devised alphabet. For a likely scenario in which the adoption of such a simplified segmental means for writing Greek would be highly valued, one might look to a setting in which literate Cypriot Greeks and non-literate Ionian Greeks served jointly in a mercenary capacity in the context of Assyrian military operations in Syria–Palestine (Woodard, 2010).

For vowel symbols, the Greeks adapted Phoenician consonantal characters that were not required for writing Greek. Thus, Phoenician *'alep*, symbol for a glottal stop (which sound Greek did not possess phonemically) was assigned the Greek value /a/ (the Greek letter *alpha*). Phoenician *he*, spelling the glottal fricative /h/, was used by the Greek adapters to record mid front (*e*) vowels (*epsilon*; for writing Greek /h/, Phoenician

ḥet was employed, the symbol for a voiceless pharyngeal fricative /ħ/). To write mid back (*o*) vowels (*omicron*), the Greeks tapped Phoenician *ʿayin*, which represented a voiced pharyngeal fricative /ʕ/. Phoenician *yod*, spelling the palatal glide /y/, and *waw*, representing /w/, were assigned the Greek values /i/ (*iota*) and /u/ (*upsilon*), respectively.

The Etruscan Alphabet

Following rapidly upon its creation, the alphabet was widely disseminated throughout the Greek world, developing many local varieties. The Phrygians of central Anatolia acquired and adapted the Greek alphabet not long after its creation. In the south of Italy, Greek colonists passed their western Greek alphabet on to a non-Indo-European people of Italy, the Etruscans, by the late eighth century BC. As the Etruscan language lacked voiced stops, the Greek letters representing such sounds, *beta* (/b/), *delta* (/d/), and *gamma* (/g/), were not needed for that purpose. The first two of these letters would disappear from the Etruscan alphabet, although *gamma* was retained and used for spelling the voiceless stop /k/ when it occurred before a front vowel. The Etruscans used Greek *kappa* for /k/ before /a/ and Greek *qoppa* for /k/ before the high back vowel /u/. In turn, the Etruscans transmitted the alphabet to other peoples of Italy.

The Roman Alphabet

Among those places to which the Etruscan writing system came was the city of Rome – a singly significant step in the history of the alphabet. For a time, the Romans continued the Etruscan practice of using three different symbols to represent the velar stop /k/ in its various phonetic contexts. However, *C* (from Greek *gamma*) was eventually used regularly for /k/ as well as for /g/ (*K*, Greek *kappa*, continued to be used for a very few words and *Q*, Greek *qoppa*, was employed before the letter *V* for spelling /k^{w}/). By the third century BC, a variant form of *C* had been introduced, namely *G*, for writing the voiced velar stop /g/. However, as *G* was assigned the alphabetic position held by Greek *zeta* (spelling the early Greek sequence /zd/, later /z/), which was not required for spelling Latin, it has been argued that *zeta*, not *gamma*, provided the raw material for the creation of the new letter *G*. Later, in the first century BC, with the influx of much Greek vocabulary, both *Y* and *Z* (spelling Greek /ü/ and /z/ respectively) were appended to the Roman alphabet.

The Alphabet Abroad

The alphabet would make its presence known, directly and indirectly, throughout the European continent and beyond. The fragmentary remains of Celtic writing from continental Europe are attested in alphabetic scripts – Etruscan, Roman, or Greek (aside from the Hispano-Celtic inscriptions written in a curious script which is part syllabic, part alphabetic). Moreover, the 'native' writing systems of both the ancient Celts of Britain and Ireland, and of the Germanic peoples of Europe are alphabetic traditions, although formally distinct from both the Greek and Roman scripts, and strikingly so in the case of Celtic Ogham, with its characters of oblique and right-angle lines. Nevertheless, it is undoubtedly the case that both Ogham and the Germanic runes found their inspiration and model in the Mediterranean alphabets. When in the fourth century AD, the Gothic Bishop Wulfila translated portions of the Bible into his Germanic language, he used an alphabetic script of his own design, based chiefly on the Greek alphabet.

The spreading of the Christian faith and the effort to ground believers in the biblical texts were – far beyond Wulfila – fundamental factors in the evolution of alphabetic writing systems. The Roman Catholic Church played a key role in the introduction and eventual establishment of the Roman alphabet across much of the European continent. Carried by the colonizing European nations, this writing system would be transported around the world, being utilized for writing European languages on all six of the populated continents, and adapted for spelling indigenous languages of Asia and Africa, as well as providing raw material for the symbols of the Cherokee syllabary of North America.

In the ninth century AD, Greek missionaries led by Saint Cyril and Saint Methodius developed writing systems, based on their own Greek alphabet, for translating the Bible into the language of south Slavic converts. One of these scripts, the Cyrillic alphabet, thrived and is the predecessor of the alphabetic scripts of various modern Slavic languages, most notably Russian.

The alphabets of both Armenian and Georgian are traditionally attributed to the fifth-century cleric, Saint Mesrop. These writing systems were based at least partially on the Greek alphabet, but their creator may have also drawn upon a Semitic consonantal script.

Writing in South and East Asia

The Indian Syllabaries

The earliest attested writing system of India is the script of the Indus Valley civilization, dating back to *c.*2500 BC. Many of the symbols are of a pictographic nature, and the number of symbols identified suggests that this writing system is logographic, possibly partially syllabic. It is, however, presently poorly understood (and an object of academic controversy) and does not appear to have been the source of the Indian syllabaries that appear in the third century BC. These scripts, Kharoshthi and Brahmi, probably developed from the Aramaic consonantal writing system. Of the two, only Brahmi appears to have survived late antiquity; its perhaps best-known form is Devanagari, the writing system of Sanskrit, as well as that of Hindi and other modern Indo-Aryan languages.

Devanagari differs notably from the Mediterranean and Mesopotamian syllabic writing systems in that rather than having a distinct symbol for each possible consonant + vowel combination, Devanagari consists of a basic set of CV symbols having the vowel value *a* (i.e., C*a* symbols). These CV symbols can be assigned different vowel values (C*i*, C*u*, etc.) by the addition of diacritic strokes (this is essentially the same strategy utilized by the Ethiopic syllabary, which traces its origins to a Semitic consonantal writing system, as apparently do the Indic scripts). Devanagari also has the capacity to transform basic CV symbols into ones representing more complex consonantal components (CCV, CCCV, etc.) through the use of

conventionalized ligatures. Such ligatures consist essentially of a C*a* symbol (representing the final member of the consonant cluster) to which a form, often highly abbreviated, of one or more other C*a* symbols is attached. Word-final consonants are spelled utilizing the appropriate C*a* symbol beneath which a diacritic mark, called *virama*, is placed, revealing to the reader that the symbol is to be read with no vowel component.

The Indian syllabaries were spread through much of Central and Southeast Asia, giving rise to writing systems for numerous languages. Not only does the Tibetan script trace its roots to India, but also the writing systems of Javanese, Thai, Burmese, Lao, and Khmer.

Chinese Writing

The earliest evidence for writing in China is provided by the Shang dynasty oracle-bone inscriptions of *c*.1200 BC. There is no clear evidence that writing developed in China under the influence of any then existing writing system; as in Mesopotamia, and perhaps in Egypt, writing seems to have appeared de novo. Like the earliest Mesopotamian writing system, the early Chinese script is pictographic in form and logographic in operation (i.e., each picture-like symbol represents an entire word). Moreover, as with both Mesopotamian and Egyptian scripts, the Chinese writing system is one that both multiplied the value of its characters utilizing the rebus principle and employed orthographic markers in order to minimize graphic ambiguity. In China, however, these markers were commonly graphically combined with the associated characters to produce compound symbols of two components – one signaling pronunciation, the other meaning. The fundamental logographic nature of Chinese writing has been preserved to the present day, and the inventory of logographic characters has steadily increased over time. While approximately 60 000 distinct characters are currently identified, about 2500 occur in common use.

Japanese Writing

The modern Japanese writing system is quite complex, probably the most so of modern scripts. The earliest attested examples of Japanese writing (*c*.eighth century AD) are executed in Chinese script. However, by the end of the ninth century, two Japanese syllabaries had appeared, evolving out of the practice of using certain Chinese characters as phonetic symbols. Both of these syllabaries remain in use alongside *kanji*, essentially logographic symbols originating in Chinese characters; in the contemporary script, a single such symbol can have multiple values. The syllabary called *katakana* is utilized for scientific terms, for foreign loans, for indicating emphasis, among still other uses. Usages of modern *hiragana* are varied as well: it is, for example, the syllabary used to spell grammatical particles and to represent affixes associated with *kanji*.

Korean Writing

As in the case of Japanese, the Korean language was first written with Chinese characters. It was in the fifteenth century AD, according to Korean tradition, that the Korean alphabetic writing system of Han'gul was invented. Credit for this script – the world's only alphabetic writing system which may not trace its roots to the Greek alphabet – is given to Sejong, a Korean king. Han'gul is a highly efficient and phonetically transparent script. Its various consonantal symbols are purported to have been designed to represent schematically the articulatory position of the tongue in producing the consonant sounds of Korean. While Han'gul is alphabetic, consonant and vowel characters are written together in such a way as to form orthographic blocks corresponding to phonetic syllables.

Writing in Mesoamerica

In addition to China, on the one hand, and Egypt and the Near East, on the other, there is at least a third region of the world, where human beings appear to have designed a means of writing without prior knowledge of any such thing, namely Mesoamerica. While the study of ancient Mesoamerican

Table 1 The Greek alphabet

Symbol	Value	Symbol	Value
Α, α	a	Ξ, ξ	ks
Β, β	b	Ο, ο	o

writing is still at an early stage, significant strides have been made since the 1970s. Of the several Mesoamerican scripts currently known, the best attested and best understood is that of the Maya, who were writing by at least the third century AD. In its fundamental characteristics, the Maya writing system is much like those of the Sumerians and Egyptians. The script's pictographic symbols, or glyphs, are logographic and syllabic in value. The latter type is used both in conjunction with logograms as well as for the phonetic spelling of words. In addition, the Maya system makes use of determinatives, like the Sumerian and Egyptian systems, to provide semantic guidance to the reader (Tables 1–3).

Abstract

Writing systems are cultural inventions for the storage and communication of information. Although only some 5000 years old and invented ab initio four times – Sumeria, Egypt, China, and Mesoamerica – writing systems have become universally adopted and now serve a fundamental set of social and personal uses and are considered by some as mankind's most remarkable technical achievement. In spite of the ubiquity of writing, its psychological study is only now taking shape. This introduction sketches some of these lines of research.

The writing systems of the world differ importantly in how they relate to spoken language. Tokening and pictographic (semasiographic) scripts relate to meanings or intentions directly with little regard to the spoken form in which that meaning could have been expressed. So-called full writing systems represent properties of the spoken language but in completely different ways. Morphophonemic (logographic) scripts represent the words or morphemes of the language; syllabic scripts represent the syllables of the language whether or not they also represent word boundaries. Alphabetic scripts represent, with varying degrees of precision, the phonemes of the language, but also by means of spaces may represent the words of the language. Not only do these differences have an effect on learning to read, they also have an important effect on the ways in which one thinks about language and consequently about the world and the mind. Writing systems provide models for thinking about speech in addition to providing a distinctive mode of communication.

Although the psychological study of *reading* and the psychology of *language* are well-established domains of research and theory, the *psychology of writing systems* and their uses, *literacy*, are relatively recent additions to the cognitive sciences. The central goal of the psychology of writing systems is to bring these two, hitherto independent, fields of study into conjunction, allowing both to be seen in a new light.

Writing systems have been neglected in psychology for two reasons. First, twentieth-century linguistics has focused almost exclusively on speech, consigning writing merely to a way of recording. The study of writing was left to specialist domains such as epigraphy and classical studies. Nonetheless, important studies of writing were produced, that by Gelb (1963) providing the foundation for more recent work (Houston, 2004; Daniels, 2009). Second, only the alphabetic writing system was the object of psychological studies of reading, leaving the impression that other writing systems were primitive and scarcely worth careful study.

In the period since the 1960s, the two fields, the psychology of reading and the psychology of language, have begun to converge to produce several lines of new research and theory represented by several handbooks and two new journals *Written Language and Literacy* and *Writing Systems Research*. Line of research make up the major sections of this article.

Relation between Speech and Writing

Making marks which can serve mnemonic and communicative purposes is as old as human culture itself. Writing systems are a subset of such marks which, typically, represent aspects of linguistic form. Sampson (1987) provided an abstract classification of types of writing system. Some systems, *semasiographic* systems, represent meanings without any direct link to spoken form. Historical examples include the so-called 'picture writing' of American Indians, more modern ones include systems of highway signs and mathematical symbols. Some writers (Coulmas, 1989; Harris, 1995) consider such nonspeech sign systems as full writing systems, claiming that what makes a writing system is its adequacy in conveying information visually rather than its purported links to speech.

Logographic scripts are linguistically based but the spoken elements represented are meaningful units, primarily words and morphemes. A clear example of such a script is Chinese in which morphemes which sound identical are represented by entirely dissimilar graphic characters, although some theorists (de Francis, 1989) insist that any full writing system is phonologically based, at least to some extent. Robertson (2004: p. 25) defines logographic signs as any sign, whether icon, index or symbol, that identifies a relation between a written sign and 'the object of the spoken sign.' A logograph, then, even if it resembles an object or event, is not a picture of an event but a representation of language.

Syllabaries are scripts which represent spoken patterns by signs for syllables. Interestingly, syllabaries are now thought to be modern inventions rather than historically step toward the invention of the alphabet (Trigger, 2004: pp. 64–65). Yet syllables are easily discriminated units of speech that play a role in children's learning to read an alphabet (Adams et al., 1998). In the Ancient Middle East, Aramaic, Hebrew, and Arabic writing systems sometimes described as syllabaries are more correctly described as consonantaries or unvocalized alphabets because of the absence of vowels. Thus the syllables *ka*, *ke*, *ki*, *ko*, for example, are written with the same graphic sign representing the consonant /k/.

Finally, *alphabets* employ a separate mark to represent the consonant and vowel segments of a syllable, roughly, the phonemes of the language. These categories of writing systems are generic types; no living writing system is based exclusively

on one type of sign but rather combinations of word signs, morpheme signs, syllabic signs, and phonemic signs. Thus in English script, signs represent both phonemes by means of letters and words by means of spaces between letter groups and sentences by means of punctuation. Japanese writing uses Chinese logographs (Kanji) to represent the stems of content words and a completely different syllabic script (Kana) to represent grammatical morphemes and inflections (Taylor and Taylor, 1995).

In one sense, the history of scripts reflects the discovery of increasingly subtle aspects of speech, going from meanings to analytical constituents of speech, namely phonemes. Although Gelb (1963) saw an evolutionary force as work that moved logograms to phonograms and eventually to the alphabet, most researchers (Gaur, 1987; Sampson, 1987; Olson, 1994; Harris, 1995; Trigger, 2004; Daniels, 2009) now argue that while writing systems have evolved to more adequately represent speech, they have done so by using iconic signs, indexical signs, and phonological signs. The Greek invention of the alphabet, once thought of as the work of genius is now seen as the result of borrowing a script invented for one language to represent a completely different language. The consequence of such borrowing was the discovery of previously ignored properties of speech, word signs, syllable signs, and signs for phonemes a pattern that bears some similarity to the processes children undergo in learning to read and write.

Writing Systems and Reading

As different types of writing systems bear distinctively different relations to speech, learning to read and write them call upon different cognitive activities. Semasiographic systems, signs that represent meanings rather than linguistic forms make no sharp distinction between drawing and writing in that they allow variable readings. Nineteenth-century Canadian Blackfoot Indians, for example, depicted 'the year that horses got drowned' by means of a circle (representing a lake) and four stick drawings of horses superimposed on the circle. Such a chronicle records an important cultural event but not the linguistic form of its description. Ancient Mesoamerica, namely the Mixtec, Aztec, and Mayan systems invented before the conquest long thought to be picture writing are now recognized as writing systems based primarily on logographs representing units of meaning that are then borrowed to represent units of sound, the so-called rebus principle (Houston, 2004).

All other so-called full writing systems map on to or represent spoken forms and learning to read each of them requires a somewhat different orientation to the script. Scribner and Cole (1981) found that their Vai subjects in Liberia in learning to read a syllabic script became adept at analyzing their speech into syllabic units but failed to analyze their speech into words. Others have found that the ability to manipulate phonemes was tied to learning to read an alphabet. Read et al. (1986) found that Chinese readers of traditional character scripts could not detect phonemic segments whereas those who could read Pinyin, an alphabetic script representing the same language, could do so.

Ample empirical evidence exists to show that it is acquaintance with an alphabetic script that is critical to the acquisition of awareness of the phonological properties of the language (Morais et al., 1979; Vernon and Ferreiro, 1999). Concepts of words as lexical entities, similarly, have been shown to be tied to concepts of words as written entities (Olson, 1994). Concepts of sentences, needed for the mastery of punctuation, are acquired at even more advanced levels of literacy. Conceptual development in children is, in part, the consequence of the acquisition of these systems for representing language (Vygotsky, 1986).

Much confusion about the cognitive and social implications of writing and reading arises from a failure to recognize that modes of reading and interpretation do not inevitably arise from simply learning to identify words and letters. The history of writing is largely a history of inventing devices, such as punctuation and text structures, as well as rules for interpretation that have taken sometimes millennia to develop. A dictionary itemizing all the words of a language is a recent literate invention. The very idea of fixity of a text is not inevitably attributed to writing and printing but to a specialized set of conventions for interpreting texts and institutional structures for preserving them (Johns, 1998). However, once procedures had been developed for the systematic interpretation of Scriptural texts, it was found that such procedures were also suitable for the interpretation of the 'book of nature.' Scientific epistemology, it has been argued, is a form of applied hermeneutics (Olson, 1994; Killeen and Forshaw, 2007).

Theories of Reading Alphabetic Scripts

Assumptions about the relation between script and language have given rise to considerable, well-publicized, differences of opinion and differences in reading theory. One group emphasized the recognition of meaning of written expressions in ways analogous to the recognition of meaning in oral forms. That is, written language is seen as an alternative to spoken language each with their peculiar and distinctive perceptual and cognitive processes but with a common goal of meaning construction, hence the label Whole Language.

The other group, credit for which is often given to Alvin Liberman and Isabel Liberman of the Haskins Group at Yale University, is that reading is essentially a metalinguistic activity in which readers must find mappings from the written form to aspects of their implicit knowledge of speech (Olson, 1994; Adams et al., 1998). Evidence on the importance of word and phoneme segmentation, two forms of metalinguistic knowledge, to learning to read and write tends to favor the metalinguistic theory of reading (Stanovich, 1986; Lundberg et al., 1988), that is, the theory that reading is not a matter of mapping signs to meanings but rather a matter of mapping visual signs to aspects of oral speech and hence on to meaning. It is this metalinguistic theory of reading that helps to explain not only why learning to read brings aspects of speech into consciousness but also why reading and writing may contribute to a new and distinctive mode of thought in certain social and institutional contexts.

Writing Systems and Thinking

Nineteenth-century theorists took the view that writing and literacy had the general effect of making thought more logical

and formal. The recognition of the fact that there are many types of writing systems and that even those different types may be read in very different ways (Saenger, 1997) has made such general claims problematic, as has the dispute as to the meaning of literacy, some identifying it with the basic skills of reading and writing (Scribner and Cole, 1981) and others with the evolved products of particular literate cultural traditions (Goody, 1968; Olson, 1994).

Although there is wide agreement on the 'psychic unity of mankind' ("They are just like you and me," as Jack Goody once put it), and there is wide agreement that all languages are *in principle* capable of expressing all nuances of meaning, nonetheless patterns of thought vary widely from culture to culture and context to context, so much so that it is not uncommon to despair of finding interesting cognitive differences attributable to writing or to a written tradition. Mathematics, the epitome of a written tradition, is sometimes seen as basically equivalent to practical computations, so-called street math.

On the other hand, cultural historians have asserted the cultural and psychological implications of writing and literacy, arguing, for example, that the medium of representation is the most important aspect of the message (McLuhan, 1962), that writing separated the knower from the known (Ong, 1992), that scriptal changes caused the origins of modern silent reading (Saenger, 1997), and that writing allowed the formulation of modern conceptions of logic and mathematics (Goody, 1968).

The metarepresentational theory of reading gives new credence to these more radical views. Writing and reading a linguistically based script, on this view, are an exercise not only in meaning, but also in consciousness and discourse about language, that is, about units of sound, units of meaning, words and structural units, sentences. Literacy on this view is seen as instrumental to discourse about word meaning, sentence meaning, and to other aspects of form which may be *mentioned* rather than *used* in discourse. This metarepresentational shift invites talk not only about particular words and sentences independently of their use, but also about other metarepresentational properties, such as *truth*, *logical form*, and *aesthetic goodness*. Furthermore, it allows mathematics to be clearly distinguished from 'street math,' the former being concerned with number rather than quantity. In the former, a number is expressed in the singular: *five* is more than *four*. In the latter, quantity is expressed as plural: I have seven apples, *five* are red. Only the former is metarepresentational, that is, mentioned rather than used, and consequently an object of thought in its own right.

Furthermore, writing is instrumental to thinking in general as a form of metalinguistic knowledge, that is, knowledge 'about' the lexical, grammatical, and logical properties of the language. Vocabulary knowledge, for example, is both greatly extended by reading (Anglin, 1993), and reflective knowledge about words, as required for judgments of synonymy, for example, serves as a major aspect of measured intelligence in a literate society (Stanovich, 1986). Formal reasoning tasks which require judgments of validity rather than truth or agreement, too, appear to be related to literacy, especially the specialized literacy of schooling (Ong, 1992; Olson, 2009).

To account for such effects ranging from phonological awareness to awareness of sentence meaning (as opposed to what a speaker means by the sentence), Olson and Oatley (2014) has proposed that writing be seen as quoted speech, and that reading and writing be viewed as learning to deal with quoted utterances rather than with ordinary direct utterances. This associates writing with a special feature of language known as reflexivity and as roughly equivalent to the use – mention distinction and language – metalinguistic distinction. Thus, in writing and reading one is not merely using an expression but quoting and thereby mentioning a linguistic form. The special interpretation called for in such a context depends upon the special properties of the form, its 'linguistic meaning' or 'sense,' rather than its referential meaning as well as allowing for judgments of similarity of meaning and judgments of logical entailments. Some writers such as Havelock (1982) and Ong (1992) argue that "all elaborate, linear, so-called 'logical' explanation depends on writing" (Ong, 1992: p. 312). Admittedly, not every culture and/or every reader exploits these distinctions as they rely heavily on particular institutional arrangements such as schools, professions, and academic disciplines. However, no reader reading a word- and sentence-segmented alphabetic text can fail to acquire the special metalinguistic concepts of sound, word, and sentence. The remainder comes with more specialized study, normally in schools.

Writing as Normative Practice

Writing does not merely transcribe speech but presents speech in terms of an idealized model. When learning to write, one is taught not to transcribe speech but rather to edit the speech by removing false starts, correcting errors, and adding needed qualifiers to make the transcription more complete, correct, and formal than the more spontaneous oral utterance. Writing in a literate culture is a normative practice, which is to say it involves the correct, authorized forms of words, sentences, and texts. Admonitions to 'speak grammatically' are in fact admonitions to speak as one would write. Although linguists abhor so-called prescriptive grammars, claiming that all utterances of a native speaker are grammatical, schools are regularly charged with teaching 'proper English.' In this way, writing comes to serve as a model for speaking.

Reading texts and composing them provide a special forum for coordinating the content of a domain with the syntactic and rhetorical demands of the written models available. van Dijk and Kintsch (1983) showed how readers coordinate linguistic form with conceptual structure in interpreting texts and Scardamalia and Bereiter (1986) showed how in writing, students coordinated their ideas with available discourse forms.

Thinking for Speaking and Writing

Slobin (1996) has suggested that the relation between language and thought be reconsidered in terms of thinking for writing and thinking for speaking as any writer will attest. Biber (1988) found important linguistic differences between spoken and written discourse especially in the informational density allowed through complex noun phrases and in the richness

and diversity of lexical choice. He attributed these differences primarily to the opportunities for editing and revision allowed by writing. Hayes (2009) has examined this composing and editing process empirically. Stromquist and Verhoeven (2004) compared the oral and written narrative accounts of a social event produced by children, adolescents. The written accounts by the oldest subjects included a vastly larger range of speech act and mental verbs to describe interactions. Berman and Ravid (2009) examined student's oral and written productions of expository texts and again found that the differences, primarily in the use of causal links, appeared primarily in the written discourse of older, college-age subjects. Snow and Uccelli (2009) have examined the complexity of structures that must be learned in mastering academic prose. These topics are examined in detail in three recent Handbooks, Bazerman (2008), Olson and Torrance (2009), and Beard et al. (2009).

Writing and Knowledge

Although all of the peoples of the world know a great deal about nature, themselves, and the social world, writing systems in the modern world have largely pre-empted such local knowledge, overwriting it with institutional forms of knowledge based on textual archives and specialized interpretive practices. Havelock (1982) suggested that writing was responsible for divorcing the knower from the known, allowing the latter to accumulate and become the subject of research and revision when the social conditions were suitable. Contemporary forms of knowledge are without exception text based, with access to these forms limited to those willing to undergo years of specialized training in the formulation and interpretation of the principle documents of the tradition. Stock (1983) called such traditions 'textual communities' and Smith (1990), a sociologist, characterizes the organization of power in contemporary society in terms of objectivized forms of text-based knowledge: "The primary mode of action and decision in … business, government, the professions … are textual. The realities to which action and decision are oriented are virtual realities vested in texts and accomplished in the distinctive practices of reading and writing" (Smith, 1990: pp. 61–62). Psychologists have only begun to explore the implications of living and working in such text-based environments.

Literacy and Social Development

Because literacy plays such a prominent role in modern societies, it is often assumed that the route to social development is through teaching people to read and write, a view supported by UNESCO. Research and practice have shown that to bring about cultural and social transformation, literacy must be seen as an activity embedded in social and cultural practice. Literacy, bureaucratic institutional structures with explicit procedures and accountability, and democratic participation are mutually reinforcing. Rather than being seen simply as a goal, literacy has come to be seen as a means to fuller participation in the institutions of the society, whether in law, science, or literature (Street, 1984), as well as a means for their transformation.

Wrongful Convictions

Marvin D Free, Jr., University of Wisconsin–Whitewater, Whitewater, WI, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The earliest recorded cases of wrongful conviction in the United States are the Salem witch trials (1692–93). Yet interest in the formal study of wrongful convictions did not emerge until the early 1930s and research into this topic did not begin to accumulate substantially until the advent of DNA testing in the late 1980s. Some of the more commonly reported factors associated with known wrongful convictions are witness error, police and prosecutorial misconduct, false confessions, use of informants/snitches, forensic errors/junk science, perjury by criminal justice officials, insufficient evidence to support a conviction, and ineffective assistance of counsel. Plea bargains may additionally contribute to the wrongful conviction of innocents. Most known wrongful convictions involve murder and rape. Recent research discloses the presence of both gender and racial differences. African Americans in particular appear to be overrepresented among those who have been falsely convicted.

Scholars frequently distinguish between *legal* innocence and *factual* innocence when analyzing wrongful convictions. The former suggests that the individual is cleared of the charges as a result of procedural errors that violated his or her constitutionally protected rights, whereas the latter implies that the individual is innocent either because he or she did not commit the crime or no crime was actually committed. Consequently, data on wrongful convictions vary somewhat from one study to another. In practice, these two definitions tend to blur, because convictions characterized by serious constitutional issues or due process errors enhance the likelihood that factually innocent persons will be found guilty.

Although no knowledgeable scholar would deny the existence of wrongful convictions, a lack of consensus exists regarding the prevalence of wrongful convictions in the United States. Although much of this variation results from differing definitions of wrongful convictions, the use of different methodologies additionally contributes to these variable statistics. Both subjective and objective approaches are used by researchers. Some researchers, for instance, ask criminal justice personnel such as prosecutors, defense attorneys, judges, and sheriffs to estimate the percentage of cases in which innocents were wrongly convicted. Using this method, Huff et al. (1996) found that 72% of their respondents thought that fewer than 1% of all criminal cases resulted in wrongful convictions. An additional 20% of their subjects believed that wrongful convictions occurred in 1–5% of all criminal cases. More recently, Poveda (2001) utilized inmate self-reports to establish the frequency with which innocent defendants are found guilty. That analysis revealed that 15.4% of the inmates in the three states sampled reported having been wrongfully convicted. Although this method undoubtedly exaggerates the problem, it should be noted that the likelihood of denying guilt varied by type of offense. Those convicted of sexual assault or some other sex offense that typically relies heavily on victim and eyewitness accounts were the most likely to report being wrongly convicted. In contrast, those who were convicted of drug-related or property offenses were the least likely to express their innocence.

Some scholars focus on a specific case in which a factually innocent individual was pronounced guilty. This case study method, although providing some depth to our understanding of the wrongful conviction process, makes generalization impossible. Still other researchers extrapolate the prevalence of wrongful convictions from known wrongful convictions. This method has resulted in an estimated error rate as low as 0.027%. More typically, however, scholars report estimates that range from approximately 3–5% of all felony cases (Gould and Leo, 2010). The scope of this problem becomes self-evident when these statistics are translated into an approximation of wrongfully convicted individuals. Using a conservative figure (0.5%) to estimate the number of wrongful convictions, one finds that almost 7500 innocent people may have been falsely convicted of index crimes (murder and nonnegligent manslaughter, forcible rape, aggravated assault, robbery, burglary, larceny-theft, motor vehicle theft, and arson) in 2000. And when the research on wrongful convictions is disaggregated by race, people of color are disproportionately represented among the cases.

The formal study of wrongful convictions in the United States is commonly associated with the publication in 1932 of *Convicting the Innocent: Sixty-Five Actual Errors in Criminal Justice* by Yale law professor Edwin Borchard. Nevertheless, research in this area proceeded rather sporadically until the publication of a study by Hugo Bedau and Michael Radelet in 1987 in the *Stanford Law Review*. In that article the authors identify 350 cases in which defendants were erroneously convicted, 23 of which culminated in execution. Interest further intensified when DNA testing began to be used to exonerate innocent persons. Over 300 individuals have been exonerated through DNA testing since 1989. Approximately 62% of the DNA exonerees are African American.

A Brief History of Wrongful Convictions

The first recorded cases of wrongful conviction in the United States occurred prior to the founding of the country. The Salem witch trials during the late seventeenth century were influenced by the Puritan view that they were chosen by God to create a place of perfection on earth. Consequently, religion permeated all aspects of Puritan social life and prohibited the

rejection of these precepts by anyone. Any abnormal behavior was envisioned as an act of the devil that required immediate action. Puritans also endured high mortality rates and ongoing conflicts with the indigenous population, which further promoted fear, hysteria, and revenge. Although the first accusations of witchcraft were against women who lived on the margins of society, the hysteria soon spread to include more respectable members of society. By the termination of these events, almost 30 people had died and at least 100 more were confined in cramped prison cells. Some were tortured for months at a time. Moreover, at least seven men were charged with being wizards and performing witchcraft (Hill, 1995). The hysteria that prevailed at the Salem witch trials points to a variety of factors that continue to be found in many wrongful convictions. The suggestibility of children to events that never occurred, the inability of a coerced confession to result in the truth, and a rush to judgment are all potential factors in wrongful convictions today.

The first known wrongful murder conviction in the United States transpired during the early part of the nineteenth century in Vermont. When Russell Colvin disappeared from Manchester, Vermont in 1812, Jesse and Stephen Boorn, his two brothers-in-law, were suspected of murder, as they had frequently voiced their displeasure over their sister's spouse. Seven years later a series of events – including buried bone fragments believed to be the remains of Colvin that were uncovered by a dog – led to Jesse Boorn's arrest. A warrant was also issued for his brother, who had moved to New York. While in jail, Jesse met Silas Merrill, a forger, who falsely testified that Jesse had confessed to clubbing Colvin during an argument. Merrill further contended that Jesse admitted to hiding Colvin's remains with the assistance of his brother and his uncle, Amos Boorn, who allegedly had cut Colvin's throat with a knife. In exchange for his testimony, Merrill was released from custody. Fearing a death sentence, Jesse confessed to the crime but placed the primary blame on Stephen, because he was in another state. Unexpectedly, however, Stephen returned to Vermont to refute the allegations against him. At this point, Jesse recanted his testimony. In a miscalculation designed to avoid the death penalty, Stephen also falsely confessed to the murder but insisted that the altercation was in self-defense. Before the trial the physicians who had verified that the bone fragments were human recanted their earlier statements. Nevertheless, confessions from both defendants and statements from witnesses that the two brothers had been seen arguing with Colvin on the day of his disappearance carried the day and both were found guilty and sentenced to death. When the Vermont General Assembly convened to review the case, Jesse had his sentence commuted to life. With Stephen's impending execution scheduled for 28 January 1820, it took a series of fortuitous events to prove his innocence. An article appearing in the 28 November 1819 issue of the New York Evening Post inspired Tabor Chadwick to compose a letter to the newspaper in which he acknowledged knowing a man named Russell Colvin when he lived in New Jersey. His letter was then read by a former Vermont resident, James Whepley, who successfully cajoled an unwilling Colvin to return to Vermont in time to prevent Stephen from being executed (Warden, n.d. (a)). This early nineteenth-century case clearly illustrates the potential harm that can arise from relying on questionable forensics, jailhouse snitches, and confessions obtained under duress, factors that continue to be associated with many wrongful convictions in the twenty-first century.

The year 1989 marks the first time that DNA evidence was used to exonerate a convicted inmate. This Illinois case involved a 16-year-old female who claimed that she had been abducted on 9 July 1977, by three men, one of whom raped her in the backseat of an automobile. A medical examination disclosed that her underpants contained several hairs and a large stain that was erroneously thought to be a seminal stain but that actually was a combination of semen and vaginal fluid. The rape kit also included a vaginal swab that was preserved as evidence. A sketch of the alleged perpetrator portrayed a young clean-cut white man with long hair. The victim later identified Gary Dotson as her assailant while viewing photographs. When he was arrested by the police 5 days after the alleged rape he sported a prominent mustache, which he could not have grown since the incident. Perjured forensic testimony, prosecutorial misconduct, and an ineffective public defender resulted in Dotson being found guilty and being sentenced in 1979 to concurrent sentences of 25–50 years for rape and aggravated kidnapping. In 1985 the victim recanted her accusations after admitting that she concocted the story to disguise the fact that she had engaged in a sexual relationship with her boyfriend earlier and was afraid that she might be pregnant. Illinois Governor James Thompson subsequently commuted Dotson's sentence to time served and placed him on parole. In 1987 Dotson was charged with a parole violation. Although the State Attorney's Office eventually dropped the charges, the Illinois Department of Corrections placed a 'parole hold' on Dotson, which required him to remain in jail while awaiting the Illinois Prison Review Board's decision. At the hearing, Dotson had his parole revoked and his original sentence reinstated. However, Dotson obtained his release from prison later that year when Governor Thompson agreed to give him 'one last chance.' Nonetheless, just 2 days later he was rearrested for an altercation resulting from a refusal to pay a contested bill at a tavern. Although the charges were later dropped, the Prisoner Review Board found Dotson guilty of a 'technical' violation of his parole and ordered him back to prison for 6 months. In August 1988, DNA testing, known as polymerase chain reaction (PCR), positively excluded him as contributor of the semen and positively included the victim's boyfriend. On 14 August 1989, all charges against Dotson were finally dropped and on 9 January 2003, he received a full pardon (Warden, n.d. (b)).

In 1993 DNA evidence was used to prove that Kirk Bloodsworth was innocent of a 1984 rape and murder conviction, making him the first person on death row in the United States to be exonerated. The incident that led to his conviction in 1985 involved the rape and murder of Dawn Hamilton, a 9-year-old child in Baltimore County, Maryland. The primary evidence used to obtain the conviction was the testimony of five witnesses who placed Bloodsworth in proximity to the crime as well as questionable forensic evidence that supposedly matched his shoes to marks on the child's body. After the Maryland Court of Appeals overturned his conviction in 1986, he was retried and found guilty again. This

time, however, Bloodsworth received two life sentences. In 1992, Centurion Ministries of Princeton, New Jersey agreed to review his case and sought DNA testing utilizing PCR technology. Tests conducted by Forensic Science Associates and confirmed by the Federal Bureau of Investigation ruled out Bloodsworth as the perpetrator. He gained his freedom on 28 June 1993, and received a full pardon from Maryland Governor William Schaefer in December 1994. In spring 2003, new stains were discovered while reviewing evidence from the cold case. These stains, which were DNA tested and compared against a national DNA database, culminated in the charging of Kimberly Ruffner with Hamilton's murder on 5 September 2003 (Warden, n.d. (c)).

Sources of Data on Wrongful Convictions

Although a number of websites contain some information on wrongful convictions, the data sources discussed in this section represent the best-known and most respected websites currently available. For those desiring an international database on wrongful convictions, the Forejustice website (http://forejustice.org) includes over 3650 cases from 102 countries dating back to the fifth century. Conveniently arranged by either location or last name, the serious researcher will find this site a trove of invaluable information both current and historical. Although the amount of information on any individual case is limited, the inclusion of cases from outside the United States makes it possible to examine wrongful convictions from different geographical locations.

With 626 documented cases in mid-2013, the United Kingdom is second only to the United States in number of reported wrongful convictions. The earliest wrongful convictions in the United Kingdom are from the sixteenth and seventeenth centuries, when almost 90 individuals were wrongfully convicted of witchcraft. An analysis of a more contemporary period (1970s and later) reveals that murder and manslaughter cases represent the single largest category among the false convictions. The dominance of this offense is illustrated by the fact that all of the reported wrongful convictions for rape and sexual assault, robbery, terrorism, and drugs fail to approach the number of innocents falsely convicted of murder and manslaughter.

Australia is another country with a substantial number of reported wrongful convictions. There were 108 Australian cases in mid-2013. As previously observed in the United Kingdom, murder (36) is the most common offense leading to a false conviction in Australia. The 14 wrongful rape and sexual assault convictions make this crime the second most common among the wrongful convictions. With 12 cases, wrongful assault convictions comprise the third most frequently occurring category.

An analysis of Canada during this same time period discloses 79 cases, the largest number of which involve murder. Wrongful murder convictions constitute approximately 42% of the cases from this country. And if manslaughter and infanticide cases are included, then this category swells to nearly half of the reported wrongful convictions in Canada. Rape and sexual assault cases are the second most common offense, mirroring the findings of both the United Kingdom and Australia.

Unfortunately, the quantity and quality of the information available for each country varies, making cross-cultural comparisons problematic at best. Twenty-six countries on the Forejustice list contain only a single wrongful conviction. Moreover, countries that tend to impede the free exchange of information derogatory to the state have few reported false convictions. For instance, there is only 1 case each from Cuba and the Russian Federation, 2 cases from North Korea, and 10 cases from China.

Of special significance on the Forejustice website is a link to *Justice Denied*, a magazine founded in 1998 by the Justice Institute, a nonprofit organization. Available in both electronic and print formats, *Justice Denied* is devoted exclusively to wrongful conviction cases. Particularly helpful is a free online index of every published article beginning with issue one. There is additionally an online bookstore with over 80 titles of books related to this subject matter.

Since the 1999–2000 academic year, Northwestern University's School of Law has been home to the Center on Wrongful Convictions (CWC). With a paid staff of five, the CWC maintains a list of exonerated individuals from state and federal courts plus the District of Columbia. Unfortunately, many of the entries are limited to the names and perhaps relevant dates of the wrongful convictions. An exception is the list of Illinois exonerations, which contains considerable information on virtually all of the cases in that state. In December 2000 the CWC began collaborating with the Innocence Project to further the development of innocence projects in other jurisdictions. The Center partnered with the University of Michigan's School of Law in May 2012 to launch the National Registry of Exonerations (NRE). Later that same year it established the first ever Women's Project. This project emphasizes both litigation and research involving falsely convicted women. Initially, the research will concentrate on cases in which wrongful convictions were obtained through false confessions and circumstantial evidence. More information about the CWC is available on its website, which can be accessed at www.law.northwestern.edu/wrongfulconvictions.

The Innocence Project is affiliated with Yeshiva University's Benjamin Cardoza School of Law in New York. Founded in 1992 by Barry Scheck and Peter Neufeld, the home page states that "The Innocence Project is a national litigation and public policy organization dedicated to exonerating wrongfully convicted individuals through DNA testing and reforming the criminal justice system" (www.innocenceproject.org). Over 300 post-conviction exonerations in the United States arranged in alphabetical order are profiled on the website. Additionally, there is a brief discussion of non-DNA exonerations with a link to a more thorough analysis of five cases.

Information on wrongfully convicted death row inmates in the United States is available at the Death Penalty Information Center (DPIC) (www.deathpenaltyinfo.org). The DPIC provides the user with an enumeration of over 140 individuals who were sentenced to death but were exonerated through acquittal of all charges related to the crime that placed them on death row, dismissal of such charges by the prosecution, or a full pardon based on evidence of innocence. This list, which is

continuously updated, includes all individuals who have been released since 1973.

The jointly sponsored NRE is the most recent entrant into the wrongful conviction arena. A product of well-respected law schools from Northwestern University and the University of Michigan, information about the NRE list of exonerees is available online at www.law.umich.edu/special/exonerations/Pages/about.aspx. A rapidly growing database, the NRE enumerates almost 1200 exonerations since 1989. This is an especially user-friendly website as the list of exonerees is arranged so that cases can be sorted by name, state, county, date of conviction, date of exoneration, whether DNA was used in the exoneration, and contributing factors. Narratives of each of the cases can be accessed as well.

Factors Associated with Wrongful Convictions

It is beyond the scope of this article to fully address the causes of wrongful convictions, as they are many and varied. Nevertheless, the disproportionality of people of color in the criminal justice data suggests the presence of racial discrimination in both legislation and enforcement of laws. Selective enforcement of the law, racial profiling, prejudice and discrimination, and poverty continue to contribute to the overrepresentation of minorities in the criminal justice system. Drug prohibition in the United States has had a particularly deleterious effect on the nonwhite population, beginning with laws that prohibited the Chinese from importing opium during the nineteenth century and continuing with the focus on crack cocaine during the mid-1980s. Although some researchers have analyzed these issues, much of the literature on wrongful convictions has concentrated instead on factors that directly result in the conviction of an innocent defendant. The remainder of this section examines these factors.

Witness error is a major problem in known wrongful convictions. Mistaken eyewitness identification was a factor in 43% of all exonerations in the United States from 1989 to 2012 (Gross and Shaffer, 2012). Psychological, systemic, societal, and cultural variables can affect one's perception. Although most eyewitness misidentification is unintentional, research has demonstrated that cross-racial identifications are most problematic. Incidents in which white subjects are attempting to identify black subjects are especially vulnerable to misidentification.

Police and prosecutorial misconduct are factors in many documented wrongful convictions as well. A study of DNA exonerations by the Innocence Project revealed that police misconduct was present in half of the cases and prosecutorial misconduct occurred in 42% of the wrongful convictions (Scheck et al., 2000). The organizational culture of the police and district attorney's office can produce a climate that enhances the likelihood of wrongful convictions if expedience and winning at all costs are emphasized. Police and prosecutorial misconduct can manifest itself in numerous ways. For instance, the police may 'coach' the witness during the lineup; employ brutality, force, or deceit to obtain a confession; plant evidence; mishandle physical evidence; or threaten potential witnesses for the defense. Similarly, prosecutorial misconduct may result from improper behavior during grand jury proceedings and the dismissal of potential jurors because of their race, ethnicity, or gender. Prosecutors sometimes use known false or misleading evidence, suppress exculpatory evidence, and withhold information that the witness for the prosecution received immunity or other rewards for testifying. Use of improper closing arguments, badgering hostile witnesses, mischaracterizing the facts and evidence of the case, and mishandling the evidence are additional potential examples of prosecutorial misconduct. The probability of a wrongful conviction is further enhanced when police and prosecutors fail to adequately investigate other potential perpetrators of the crime and ignore evidence that fails to corroborate their preconceived views.

False confessions are more likely to occur in cases in which the defendant is a juvenile, has a mental deficiency, or has been interrogated over a sustained period of time. A 2012 study by the NRE disclosed that juveniles were five times more likely to falsely confess than adults. Further, mentally disabled individuals were nine times more likely to falsely confess than individuals without such deficiencies (Gross and Shaffer, 2012). Duress, coercion, intoxication, a misunderstanding of the law, fear of violence by the police, actual harm by the police, the threat of a harsh sentence if a confession is not forthcoming, and a misunderstanding of the situation also affect the probability of a false confession. The extent to which false confessions contribute to the wrongful conviction of innocents varies in the research. A report that examined wrongful convictions in Illinois, for example, found that false confessions played a role in about 53% of those convictions (Warden and Fredrickson, 2012). In contrast, false confessions accounted for only 16% of the exonerations in the United States as a whole from 1989 to 2012 (Gross and Shaffer, 2012).

Although the Innocence Project suggests that over 15% of DNA exonerations involve the use of informants/snitches, about 46% of all death row wrongful convictions examined by the Center on Wrongful Convictions involved the testimony of witnesses with incentives to lie. In many of these cases the jury was unaware that the informant/snitch had an agreement with the prosecutor to either get a charge reduction or to be released in exchange for incriminating testimony (Warden, 2005). Moreover, racial disparity in drug enforcement may be exacerbated through the use of informants in minority communities. Because law enforcement typically focuses its attention on high-crime urban communities where people of color are more likely to reside, and given the incentive that informants have to lie, inhabitants of these areas are at greater risk of "false accusations, mistaken warrants, erroneous raids, and wrongful convictions" (Natapoff, 2009, p. 113).

In the late 1980s the utilization of DNA evidence to exonerate the innocent and to convict the guilty represented a milestone in the discovery of wrongful convictions. Although DNA analysis has benefitted from extensive research, other forensic techniques such as hair analysis, bite mark comparisons, firearm tool mark analysis, and shoe print comparisons have not received similar scrutiny, yet they have been used to convict innocent individuals. Even cases involving DNA evidence may be subject to contamination, distortion of findings, mislabeling, as well as other issues. Nor is this problem

isolated to a few incidents. The Federal Bureau of Investigation, the US Army Criminal Investigation Laboratory, as well as laboratories in various states have all been accused of the improper handling of forensic evidence in the recent past. According to the Innocence Project, unvalidated or improper forensic science is a factor in approximately half of the DNA exonerations.

Perjury by criminal justice officials, insufficient evidence to support a conviction, and ineffective assistance of counsel complete the list of commonly reported factors in the wrongful conviction literature. Ineffective assistance of counsel is undoubtedly underreported in the literature because of its subjective nature. Nonetheless, it is potentially problematic since a strong defense can deter a wrongful conviction. Insufficient funding, lack of mechanisms for monitoring the quality of legal representation, an unmotivated defense counsel, the presumption of guilt that pervades the criminal justice system, and the difficulty of proving the presence of ineffective counsel on appeal can influence this process.

Although not as frequently identified in the literature, plea bargains may lead to wrongful convictions. A plea bargain may look attractive to an innocent defendant with a prior record or one who does not qualify for a public defender. And with their limited resources, innocence projects are more likely to devote their attention to cases involving extended sentences or the death penalty, thereby excluding many plea-bargained cases.

Wrongful Convictions in the United States

Before discussing wrongful convictions it should be noted that many false convictions go undetected. Organizations that defend wrongfully convicted clients have limited financial resources and tend to concentrate on the most egregious cases, thereby potentially ignoring many cases in which a defendant is falsely convicted but the circumstances do not lend themselves to an easy legal remedy. Moreover, cases in which wrongfully accused defendants receive probation or suspended sentences are less likely to be perceived as warranting the expenditure of precious capital by organizations that defend the innocent. Defendants with few financial resources may also be more willing to accept erroneous guilty verdicts. And because wrongly convicted defendants may possess a prior criminal record, there is frequently little outcry from the public to correct these miscarriages of justice. With these caveats in mind, an analysis of known wrongful conviction cases is in order.

A comprehensive review of known wrongful convictions in the United States was conducted by Samuel Gross and Michael Shaffer at the NRE in 2012. They examined 873 exonerations from January 1989 through 1 March 2012. Some of the more salient findings appear below.

- Almost all of the exonerations involve male defendants. Only 7% of those exonerated were female.
- Minorities comprise the largest number of exonerations. Half of the people exonerated were African American. Whites, Hispanics, and American Indians or Asians represented 38, 11, and 2% of the exonerated population, respectively.
- Although only 37% of the exonerations are the result of DNA evidence, the use of DNA in wrongful conviction cases is increasing.
- Wrongful convictions are not distributed evenly throughout the United States. Illinois, New York, Texas, and California led the United States in exonerations.
- The vast majority of exonerations are for the offenses of murder and rape. Almost half of the exonerations were homicides, whereas sexual assaults accounted for over one-third of the exonerations.

The study additionally investigated factors that contribute to false convictions. As other scholars have observed, wrongful convictions frequently result from the culmination of multiple factors. Slightly over half of the wrongful convictions included perjury or false accusation. Mistaken eyewitness identification (43%) and official misconduct (42%) were the second and third most important contributors to wrongful convictions. Approximately one-fourth of the cases disclosed the presence of false or misleading forensic evidence, whereas false confessions were a problem in 16% of the false convictions. The investigation further revealed that the frequency of these factors varied according to the type of offense. For instance, mistaken eyewitness identification was the primary contributing factor in both sexual assault and robbery exonerations, although perjury or false accusation was the most common contributing factor in homicide exonerations.

African Americans and Wrongful Convictions

Minorities in general and African Americans in particular are overrepresented at every stage of the criminal justice system. On any given day, for instance, 10% of all African American men in their 30s are either in jail or prison. Because blacks comprise the largest racial/ethnic category of exonerated individuals in the United States, this section examines black wrongful convictions in greater detail.

A small, albeit growing, segment of the literature on wrongful convictions focuses on African Americans. In *Convicted but Innocent: Wrongful Conviction and Public Policy*, Huff et al. (1996) found that African Americans were overrepresented in wrongful convictions. The authors argue that witness misidentification (especially in cases involving white witnesses and black suspects) and prejudice by police and prosecutors, along with other factors, were responsible for this disparity. More recently, an examination of US exonerations from 1989 to 2003 documented racial disparities, particularly in rape cases and those with juvenile defendants. Although the data did not permit a determination of the reasons for these disparities, the authors speculate that cross-racial misidentification in many of the interracial rape cases contributed to the false convictions in addition to racial bias and discrimination. They further note the potential negative impact of "a dual system of juvenile justice …, one track for white adolescents, a separate and unequal one for black adolescents" (Gross et al., 2005, p. 551).

Marvin Free and Mitch Ruesink (2012) provide a detailed analysis of 343 wrongfully convicted African American men in their book, *Race and Justice: Wrongful Convictions of African*

American Men. Classifying their cases according to the most serious offense that led to the wrongful conviction, they found that slightly over half of the false convictions were for murder/attempted murder. Nearly one-third of their wrongful convictions involved rape and sexual assault. However, fewer than 12% were drug-related and fewer than 5% were robbery cases. Although wrongful convictions occurred in 31 states plus the District of Columbia, the cases were unevenly distributed. With 52 false convictions, Texas headed the list, followed closely by Illinois, which had 47 wrongful convictions. Ohio was the third-highest state with 26 cases.

There were 174 murder/attempted murder cases in the study. Most commonly, the case involved a single charge of murder. When additional charges were present they usually involved rape/sexual assault and/or robbery. Typically multiple factors contributed to the failed justice. Witness error (42.5%), police misconduct (38.5%), prosecutorial misconduct (36.2%), and use of informants/snitches (33.3%) were the most common factors associated with these wrongful convictions.

As noted earlier, rape/sexual assault ($n = 109$) was the second most common offense category. An analysis of these cases revealed that almost 70% of these wrongful convictions included at least one additional charge, the most frequent of which was robbery. Of particular note was the significance of witness error in rape/sexual assault wrongful convictions. Witness error was a contributing factor in almost 93% of the cases. And in many instances it was the primary or only factor that was responsible for the erroneous conviction. Forensic errors were a distant second place, being found in over 30% of the convictions for rape/sexual assault. Police misconduct (about 23%) and prosecutorial misconduct (about 15%) were the third and fourth most common factors identified in the study.

Women and Wrongful Convictions

Most of the wrongful conviction literature focuses on wrongly convicted men, because most known wrongful convictions are for murder and rape. Thus, false convictions tend to be framed as a male problem. Yet the Bureau of Justice Statistics reveals that the number of incarcerated women in the United States increased almost sixfold from 1980 through 2011 and 1 in every 56 women will be incarcerated during her lifetime. Although only 7% of US exonerations from 1989 through 2012 involved women – a figure comparable to the distribution of women in the prison population – women are more likely than men to be incarcerated for crimes for which there is seldom biological evidence that can be subjected to DNA testing. Consequently, many cases in which women have been falsely convicted are overlooked. Although the literature in this area is still in its infancy, a sparse but slowly emerging body of research suggests that meaningful gender differences exist in wrongful convictions. For instance, false female convictions are more likely to be based entirely on circumstantial evidence than false convictions of men, according to Rob Warden, the executive director of the CWC. There is also evidence that suggests that female defendants who are commonly accused of harming their children or other intimates may be more easily induced to provide false confessions during police interrogations than their male counterparts.

Research on wrongly convicted women in the United States by Konvisser (2012) uncovered 138 exonerations and pardons involving women since 1900. Her study further revealed that 70% of the female exonerees were white. African American women and Hispanic or Latina women comprised 28 and 4% of the cases, respectively. Many of the women in her sample had been falsely convicted of nonexistent crimes. Murder (33%) was the most common offense with which the wrongly convicted women had been charged. An additional 15% had been charged with some form of child abuse or neglect. Drug-related charges were found in 12% of the cases. The remainder of the cases included a potpourri of diverse crimes.

An earlier study in this area examined more contemporary wrongful convictions. Utilizing two large electronic databases Ruesink and Free (2005) developed a list of wrongly convicted women in the United States since 1970. They then compared their sample with a random sample of male false convictions taken from the Forejustice database. Their results revealed that male wrongful convictions were more likely to include charges of murder and rape, whereas female wrongful convictions were more likely to include charges of child abuse. When factors associated with wrongful convictions were analyzed, again gender differences were present. Although witness error and overzealous or unethical police and prosecutors were the first and second most common factors associated with known wrongful convictions in general, the rank order of these factors was reversed in female wrongful convictions. The importance of unethical police and prosecutors was particularly pronounced in female false convictions, being present in 86% of the cases. An analysis of the racial identity of their subjects disclosed that 37% of the falsely convicted women were black. Racial differences were also detected. African American women were more likely to be wrongly convicted of murder and drug-related offenses, whereas white women were more likely to be wrongly convicted of child abuse. And finally, the two most common factors associated with false convictions among black women were perjury by criminal justice officials (53%) and prosecutorial misconduct (40%). In contrast, the two most common factors leading to wrongful convictions among white women were prosecutorial misconduct (35%) and coerced confessions (27%).

This article is reproduced from the previous edition, volume 24, pp. 16644–16647, © 2001, Elsevier Ltd.

Abstract

Wundt was a pioneer of modern psychology. The article begins with a brief biography and characterization of the historical context in which Wundt lived. It proceeds with an overview of his work and influence. His major work is introduced: the fundamentals of his 'individual psychology' and his 'ethnopsychology' are presented with their subject matter and methods. The following section describes Wundt's contributions to the genesis of the disciple of modern psychology and situates his life's work within the history of recent psychology. The question as to his transitory or enduring influence is posed in the final section, which offers a brief evaluation of his work and influence from today's standpoint. This section also contains a brief characterization of some of Wundt's important pupils and their continuation of his work in their home countries.

Life and Times

Wilhelm Maximilian Wundt was born on August 16, 1832 in Neckarau, Germany. From 1844, he attended secondary schools in Bruchsal and Heidelberg. He enrolled at Tüingen for medical study in 1851, then went to Heidelberg, where he earned his doctorate in 1856 with a work 'On the Behavior of Nerves in Inflamed and Degenerated Organs.' In Heidelberg, neuroanatomist Friedrich Arnold and the clinician and pathologist Ewald Hasse guided his interest toward neuroanatomical and neurophysiological problems. During the summer of 1856, he worked under Emil Du Bois-Reymond (1818–96) at the famous physiological laboratory founded in Berlin by Johannes Peter Müller (1801–56). Returning to Heidelberg, he became Hasse's assistant. He completed postgraduate work in physiology in 1857.

In 1858, Hermann Helmholtz (1821–94) was made professor at Heidelberg. Wundt was made professor of Anthropology and Medical Psychology in 1864. For 16 years, he worked alongside Helmholtz at the Physiological Institute in Heidelberg. During this period, his orientation shifted from experimental physiology to physiological psychology, and finally to philosophy. From 1864 to 1868 he was a representative to parliament in the state of Baden, where he advocated social integration for workers. He was appointed professor of Inductive Philosophy (philosophy of science) in Zurich, Switzerland in 1874. On October 18, 1875 he accepted a professorship in Leipzig in Philosophy ('with a natural scientific orientation'). In Leipzig, he founded the world's first Institute for Experimental Psychology, which soon attained international renown. Students came to Leipzig from many countries, including Bulgaria, the UK, Japan, Canada, Poland, Romania, Russia, and Hungary, and especially from the USA. Many students went on to establish institutes in their home countries, using the Leipzig Institute and its course of study as their model. In 1881, Wundt founded one of the world's first journals of psychology, *Philosophical Studies*. Wundt died on August 31, 1920 in Groβbothen near Leipzig, and was buried in the professors' section of the South Cemetery in Leipzig.

What kind of an era did Wundt live in? In the year of his birth (1832), the celebrated writer of German classical literature Johann Wolfgang von Goethe died. In 1848, the revolution that sought to achieve democratic process in Germany failed. In 1871, the Second German Reich was born after the violence of Prussia's wars against Denmark (1864), Austria (1866) and France (1870–1), and Austria was excluded from the German states' centuries-long common political development. By the time Wundt died (1920), the Second German Reich had lost World War I in 1918 and the Weimar Republic had been established. Looking back, Wundt wrote in his memoirs: 'Lived experience is the most immediate of what the gods have bestowed, but knowledge is the better portion of what he has been granted' (Wundt, 1920, p. iv).

Work and Influence

An Overview

Early in his career, Wundt focused on the experimental analysis of physiological and then psychophysiological problems. Somewhat later, he attempted to provide a philosophical foundation for his experimental work. The titles of his works published in Heidelberg vividly illustrate his path: *Contributions to the Science of Muscle Movements* (1858), *'Contributions to the Theory of Sense Perception'* (1859–62), *Lectures on the Mind of Humans and Animals* (1863), *Textbook of Physiology* (1864), *Physical Axioms* (1866), *Handbook of Medical Physics* (1867), and *Principles of Physiological Psychology* (1874). In 1902, one of his first biographers summarized: 'Evidently, it was involvement with questions of sensory physiology that first awakened in Wundt the need for a philosophical orientation' (König, 1902, p. 23).

In Heidelberg, Wundt also developed the fundamentals of his ethnopsychology *(Völkerpsychologie)*, stimulated by the work of Moritz Lazarus (1824–1903) and Hajim Steinthal (1823–99) in their *Journal for Ethnopsychology and Linguistics* published from 1859. Decades later in Leipzig, Wundt elaborated these fundamentals into a 'general psychology' and a 'general developmental psychology.' After 1875, he wrote the works that would bring him world renown as a methodologist, experimental psychologist, and ethnopsychologist. This progression, too, can be traced in the titles of his books: *System of Philosophy* (1889), *Logic: An Investigation of the Principles of Knowledge and Methods of Scientific Research* (finally a three-volume work, 1906–8), *Introduction to Philosophy* (1901), and the 10-volume work *Ethnopsychology* (1900–20). Between 1908

and 1911, he also expanded *Principles of Physiological Psychology*, his standard work on experimental individual psychology,' to three volumes. His students in Leipzig carried out the psychological experiments that would fill the 20 volumes of his *Philosophical Studies* and those of the subsequent *Psychological Studies*.

Wundt's Major Work – Individual Psychology and Ethnopsychology

Wundt's major work was devoted to psychology, which was for him the basis of philosophy. His psychology had a twofold basis, consisting of a scientifically oriented experimental 'individual psychology' and a humanistically oriented comparative 'ethnopsychology.' About his individual psychology, he wrote, 'The concept of individual psychology covers investigations whose subject are the psychological processes of individual human consciousness, inasmuch as these possess a *typical*, generally valid significance for normal consciousness' (Wundt, 1908, p. 162). He added, with regard to methodology, 'In truth, there are ... for individual psychology ... *two* aids available: casual self-observation and experimental method. The former assumes both a preparatory and a supplementary function; the latter, however, is the sole tool for analysis of elementary psychological processes' (Wundt, 1908, p. 163). 'Ethnopsychology,' in contrast, had' ... the task of complementing individual psychology with information about the general mental products of social life' (Wundt, 1908, p. 163). ' The principle domains of ethnopsychology ... are: *language, art, myth* and *customs*. They signify for the consciousness of cultures what imagination, feeling, and will signify for individual consciousness' (Wundt, 1908, p. 232). Clarifying the main aspects of ethnopsychology he continues, 'So the psychological value of language consists primarily in expressing laws of *thought*, therefore various forms of language correspond to specific steps in the development of this basic mental function. In the same way, *myth* is intimately connected with the activities of fantasy in *art*' (Wundt, 1908, p. 232). Finally, he describes the psychological value of (social) customs, writing, 'As myth does for art and religion, so do *customs* possess a central significance in their relation to two other important areas of life' (Wundt, 1908, p. 233). 'One of these areas is *society* ... It is society that first makes possible the formation of customs, the prevailing embodiments of norms of will within a society ... The other area deriving from customs is *law*' (Wundt, 1908, p. 234). He adds finally: 'Language, art, myth and customs are thus not the sole objects of ethnopsychology, but they are the ones that from the beginning express social life' (Wundt, 1908, p. 234). On methodology in ethnopsychology, he wrote, 'The fundamental method of ethnopsychology ... is ... *comparison* in the ways it is generally used in the humanities' (Wundt, 1908, p. 240). And he adds, '... ethnopsychology ... is conducted ... by assembling for comparison a collection of facts about psychological viewpoints, and through this close and direct connection to psychological analysis, comparison itself leads to the establishment of psychological laws . In this manner, the correct use of the comparative method here gains a significance similar to that of experimental procedure in individual psychology' (Wundt, 1908, p. 240).

With these ideas, Wundt created a conceptual framework that would have great consequence in the history of psychology: a scientific psychology of elementary psychological phenomena and a humanistic psychology of higher psychological phenomena. Scientific psychology is an 'individual psychology' since it gets its data from the experimental investigation of individuals. Humanistic 'ethnopsychology' is a 'general psychology,' since it examines general psychological objects. As such, it is also a 'general developmental psychology' since those objects also develop throughout history. Methodologically, ethnopsychology gets its data from the ethnological analysis of historically developed products of mind (i.e., language, art forms, myths, customs). From these, conclusions can be drawn about the psychological processes involved in their emergence. Such processes include thinking, feeling, or willing. The view that a methodical humanistic approach was the only way to study higher psychological processes was momentous in the history of psychology. According to this concept, there could be no experimental psychology of thinking, emotion, or volition. From today's standpoint it should be noted that Wundt did recognize that psychological methodology could not be solely experimental. It must also be a quasi-experimental and historical methodology. On the other hand, his view that higher psychological processes were inaccessible to experimentation proved to be false. Wundt's methodological quarrel at the beginning of the twentieth century with members of the Würzburg school around Oswald Külpe (1862–1915), which concerned the role of experimentation in the psychology of thinking, had already shown that his critique of their method as 'interrogation experiments' was untenable.

Wundt and the Genesis of the Discipline of Modern Psychology

Wundt made fundamental contributions to the genesis of the discipline of modern psychology in the nineteenth and twentieth centuries, in Germany and beyond. This genesis may be described generally in terms of six phases and their corresponding developmental features.

First, Wundt had a lasting impact on the development of the subject matter and methods of empirical psychology since the beginning of the nineteenth century with his 'individual psychology.' This is also true to a certain extent for his 'ethnopsychology,' if historically developed products of mind are regarded as historical empirical experience.

Second, Wundt was influential in institutionalization, that is, founding institutes for experimental psychology and anchoring them in the university system, as well as other forms of institutionalization, such as the founding of scholarly journals and scholarly societies. Active in scientific policy making, Wundt made a definitive contribution to institutionalization by founding the world's first psychological laboratory, the Institute for Experimental Psychology at the University of Leipzig in 1879. He also founded one of the first experimental journals in psychology, *Philosophical Studies* in 1881.

Third, Wundt can be said to have contributed to the temporary division into major schools during the period between about 1890 and 1940, inasmuch as his institute became a model for psychological institutes in many countries. But he did not found an actual school in the strict sense of the Berlin school of Gestalt psychology, the Würzburg school of cognitive psychology, or the Vienna school of psychoanalysis.

The fourth phase is the development of applied psychology, that is, through the inclusion and development of fields of praxis outside the universities and higher education after about 1890. Wundt had an ambivalent, rather negative relationship to the development of applied psychology. In his opinion, psychology should attempt a transition to practical applications only after its foundation has been systematically constructed (Wundt, 1913).

Fifth, with his twofold psychology and with numerous students from many countries, Wundt made a definitive contribution to the development of a pluralistic system of psychology and to the gradual integration of the major schools after about 1930.

The final phase is professionalization, that is, the establishment, social anchoring, and state certification of standards for academically educated psychologists active outside of the university system around the time of World War I. With his early work in developing a curriculum for the education and training of psychologists, Wundt contributed indirectly to professionalization. This curriculum, with further contributions from other psychologists, was adopted in 1941 in the form of the first state diploma examination regulations in Germany.

The genesis of the discipline described above was initially, in the nineteenth century, determined primarily by experimental psychology. This constituted the first phase of methodological development in which experimental methods, the technical apparatus and the mathematics of experimental physics and of experimental physiology were transferred to psychology. Wundt's 'individual psychology' is an expression of this development. It thus becomes understandable why many of the 'pioneers' of modern psychology, Wundt's contemporaries in nineteenth-century Germany, were trained as experimental physicists or experimental physiologists. They include Ernst Heinrich Weber (1795–1878), anatomist and physiologist, Gustav Theodor Fechner (1801–87), doctor and physicist, and Hermann von Helmholtz (1821–94), physiologist and physicist.

During the second half of the nineteenth century a second phase of methodological development began. More or less standardized nonexperimental methods were added step by step to the experimental procedures. These methods were initially analytical documentary procedures that Wundt called methods of 'comparison' within his 'ethnopsychology.' Later they also included the preexperimental empirical methods based on the paradigms of assessment, achievement, arrangement, and interpretation. These methods contributed significantly to the development of psychodiagnostic procedures. Both groups of nonexperimental procedures today constitute elements of 'historiographic' and 'quasi-experimental' methodology in psychology. Wundt's work and its influence may be categorized within these two phases of nineteenth-century methodological development: his experimental 'individual psychology' falls within the first phase and his nonexperimental 'ethnopsychology' within the second.

Review and Outlook – What was Transitory, What Endures

Four achievements of Wundt's life's work must be especially emphasized. First, he contributed, in the politics of science, to the genesis of the discipline of modern psychology, that is, to its independence as an empirical psychology with its own subject matter and methods. Second, he constructed a system of psychology as an experimental 'individual psychology' and as a humanistic 'ethnopsychology.' Third, he founded the world's first Institute for Experimental Psychology, which gave impetus to the institutionalization of psychology and fourth, he founded one of the first scientific journals for psychology, *Philosophical Studies*.

Critically it should be noted that Wundt's concept of the experimental inaccessibility of higher psychological processes played a limited role for a time in the discipline's development. However, even some of his contemporaries did not share this idea. They included Gustav Theodor Fechner (1801–87), Carl Stumpf (1848–1936), Hermann Ebbinghaus (1850–1909), Georg Elias Müller (1850–1934) and Oswald Külpe (1862–1915). Nor did many experimental psychologists of the next generation, such as Narziß Ach (1871–1946), Karl Bühler (1879–1963), Max Wertheimer (1880–1943) or Otto Selz (1881–1944), share Wundt's view.

Wundt's writings and activities attained worldwide influence, especially because of his many students. It was them, most of all, who spread the tradition of experimental 'individual psychology.' Granville Stanley Hall (1844–1924), who established the second psychological laboratory in the USA at Johns Hopkins University in Baltimore in 1883 and in 1887 founded the *American Journal of Psychology*, was a prime example. Another was James McKeen Cattell (1860–1944), Wundt's first assistant in Leipzig, who occupied the first chair in psychology in the USA at the University of Pennsylvania in 1887. He became known primarily as the cofounder of the field of psychological diagnostic testing. Edward Bradford Titchener (1867–1927) who left Oxford, England in 1890, spent two years in Leipzig and went on to promulgate Wundt's teachings as structuralism at Cornell University in the USA. Another student was Dimitrij Nikolaevich Uznadze (1887–1950), founder of the Georgian school of psychology and known for his theory of set. Notable among Wundt's German students were Emil Kraepelin (1856–1926), one of the founders of modern psychiatry, psychopharmacology, and experimental psychodiagnostics; Ernst Meumann (1862–1915), founder of experimental pedagogy; Theodor Lipps (1851–1914), an exponent of experimental esthetics; Hugo Münsterberg (1863–1916), founder of industrial psychology and cofounder of applied psychology ('psychotechnics'); and Karl Marbe (1869–1953), one of the founders of forensic psychology.

Xenophobia and Nativism

Peter Hervik, Aalborg University, Aalborg, Denmark

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In everyday terms, 'xenophobia' is now used to refer to dislike of foreigners, such as being anti-immigration, antiforeign, and/or anti-different groups, while 'xenophobia' in the social sciences has imported semantic changes that reflect mega-events such as 9/11, the Danish Muhammad cartoon crisis of 2005–06, and the bombing and killings on 22 July 2011 in Norway. In this new development, xenophobia (including Islamophobia) and nativism embrace the idea of cultural incompatibility and the naturalization of xenophobic attitudes following from it. Out of this understanding of xenophobia as a natural reaction, antimigration springs as a nativist necessity with a right to defend 'one's culture' while either legitimizing racism or denying that cultural and political self-defense can be racist.

Introduction

In its broadest sense, xenophobia refers to 'fear of strangers' and is associated with sentiments of antimigration. In recent years, xenophobia has emerged as an exclusionary ideology, associated not least with indiscriminate anti-Islamic beliefs and practices. From being used predominantly in North America for the last couple of hundred years, the term 'nativism' now also appears in Europe and elsewhere. It refers broadly to a favoring of established inhabitants over newcomers that eventually leads to the marginalization and exclusion of the latter.

The meanings of these two terms overlap in their association with bigot and exclusionary ideologies, which operate (like all ideologies) with explicit constructions of positively represented and defended in-groups and attacks on negatively rendered out-groups. Conceptually they can be approached as varieties of cultural racism – along with anti-Semitism; anti-black, anti-Roma, and anti-Gypsy racism; and others – as they construct distinct cultural identities that are seen as inherited, rather than as acquired through naturalization.

The word xenophobia comes from the Greek 'xenos,' meaning both the stranger and the guest, and 'phobos,' meaning fear; therefore, the term is literally 'fear of stranger.' Anatole France may have been the first to use the term 'xenophobia' in Europe, in his novel *Monsieur Bergeret à Paris* (1901).

In many languages, xenophobia is used as the supposedly less morally reprehensible word for 'racism' (Stolcke, 1995), while the more correct meaning we can find in the German term *Fremdenfeindlichkeit*, or hostility toward strangers. In this manner, the meaning of xenophobia holds the double sense of 'fear of the stranger' and 'hatred of strangers.' Although the stranger whom one fears can be welcomed as a guest, the stranger whom one hates cannot.

The hated stranger may be constructed as opposed to one's own identity and therefore negated. This negation, in Balibar's (2005) words, stems from a collective self-understanding as the other's other: the collective self receives its identity from being the other of the external collective other. In Huntington's (1996: p. 21) thesis, the 'hated stranger' is constructed within the opposition of "Unless we hate what we are not, we cannot love what we are." This resembles the formulation by Carl Schmitt (1996 [1932]), a prominent German ideologue during the Nazi period and one of the founding father figures of neoconservatism: "We don't know who we are, if we don't know our enemies."

The distinction between the feared guest and hated enemy may help us to understand that the presence of 'phobia' in 'xenophobia' is almost exclusively metaphoric. The phobia part of xenophobia carries the risk of treating the phenomenon as an illness and a form of irrationality (Rattansi, 2005: p. 295), even when used as a metaphor. While the psychological point of view associates phobias with physiological symptoms such as uncontrollable anxiety, shortness of breath, and chest pain, in the anthropological perspective, xenophobia refers to social and cultural meanings that these phobias represent.

While nativism has been present in practice since the sixteenth century in North America, it is most strongly associated with the early nineteenth century (the era of immigration), when the first book on nativism, *Political Nativism in New York State*, appeared in 1901. Earlier, Samuel Morse, a founding figure of American nativism, published the two books *The Foreign Conspiracy against the Liberties of the United States* (1834) and *The Imminent Dangers to the Free Institutions of the United States through Immigration* (1835). The emergence of nativism by the beginning of the nineteenth century was shaped by decades of anti-Catholicism, the source of antebellum nativism, which was possibly nourished by claims that Catholics were primarily loyal to the pope, and therefore could not be loyal citizens in the new United States but were instead

coming to subvert American liberty and democracy (Billington, 1938). A few years later, the newly born nativist ideology yielded a physical manifestation in Philadelphia in 1844, when nativist riots broke out. In the same year, the American Republic Party was founded and soon included the nativist Know Nothing Party.

Historian John Higham (in Michaels, 1995: p. 2) defined nativism in the US context as "intense opposition to an internal minority on the grounds of its foreign (i.e., 'un-American') connections." In anthropology, Ralph Linton and Irving Hallowell (1943: pp. 230–240) discussed nativism as "any conscious, organized attempt on the part of a society's members to revive or perpetuate selected aspects of its culture." The conscious, organized attempt was understood to lift the effort above a 'normal process' of what could best be seen as ethnocentrism. The stress on consciousness also conveys awareness that "there are cultures other than its own and that the existence of its own culture is threatened" (Linton and Hallowell, 1943: pp. 230–240). Thus, the semantic scope of nativism ranges from an ethnocentric belief of a community (or part of a community) to an ideology of social and nationalist movements.

In sum, xenophobia and nativism are both exclusionist ideologies claiming the rights to defend one's cultural difference. Xenophobia's fear and hatred of the stranger embody a call for cultural self-defense. Similarly, the nativist reliance on the neoracist maxim that different cultures are of equal value but essentially incompatible with each other (Hervik, 2011) is one that constructs a "culturally defined in-group," explained by Walter Benn Michaels (1995: p. 80) as follows: "If to belong to a culture you must be able to encounter it in the form of memory, as a tradition that is already yours, then no one can ever cease to belong to his or her culture or begin to belong to some other culture." This is where the right to claim cultural rights is born.

Current Usages

The usage of 'xenophobia' and 'nativism' is widespread in everyday language and currently under heavy scrutiny in social science research. In everyday discourse, xenophobia is now used to refer to dislike of foreigners or to holding beliefs that are anti-immigration, antiforeign, and/or anti-different groups, while xenophobia in the social sciences has imported semantic changes that reflect recent mega-events and comprehensive changes.

From a social psychological perspective, xenophobia is approached as a person's uncontrollable fear of the difference of people, who are often associated with racial, cultural, or religious difference. This version of xenophobia highlights the anxiety disorder, the irrational and literally 'phobic' fear; in this case, the central feature of xenophobia is, like with all social phobias, an excessive fear of being observed or scrutinized by unfamiliar persons (Furmark, 2000). The social psychological approach has declined in importance next to the drastic growth, in the social sciences and humanities, of findings relating to terrorist attacks and the contestation of Muslim cultural integration. In these approaches, xenophobia and nativism are seen as yet more sociocultural constructions, where dislike (if not hatred) of others is learned through socialization process, especially by way of news media coverage and popular culture.

With events such as the World Trade Center bombing in 1993, the bombings of the American embassies in Kenya and Tanzania in 1998, the 9/11 attacks in the United States in 2001, the bombings in Madrid in 2003, the bombings in London in 2005, the Muhammad Cartoon Crisis beginning in Denmark in 2005–06, and the so-called 22/7 massacre in Norway in 2011, as well as a series of smaller scale events and subevents, it became clear that definitions of xenophobia and nativism had to move beyond reducing these acts of cultural racism to simply discriminatory attitudes or sentiments. Instead, these definitions must include the level of social action, or practice, where state-supported policies and social movements played a role. In the aftermath of these events and what they represent, the conceptual implications and the analysis of the events from anthropological and sociological perspectives present us with a huge and urgent challenge.

Anchoring definitions of cultural racism in its various forms can also be seen at the level of situated social interaction. An incident in Denmark is useful for illustration. Two black men were denied entrance to a nightclub there on the basis of their visible difference from other customers, an appearance that the security guards associated with sub-Saharan African men. However, the moment they realized that the guests were African-Americans, they were immediately welcomed. In this case, the rejection can hardly be reduced to xenophobia in the strict social psychological sense, with an emphasis on 'phobia.' An analysis of institutional support of acts of exclusion must be included: the nightclub's policies and its employees' actions, municipal and state policy on intervening or not intervening, the role of the police, and so on.

Another peril in the study of xenophobia (which can also be illustrated by the nightclub incident) is when an incident is being talked about both as xenophobic and as racist discrimination. We may note, for illustrative purposes, that the term is regularly used to describe intense dislike of foreigners or migrants as well as the racist act of rejection on the basis of one's skin color and association with the non-Western world. The term may appear as less morally reprehensible than racism, since everyday uses of 'race' and 'racism' are negatively loaded words in most countries, especially in the German-speaking countries of Central Europe. Here, the words *Rasse* and *Rassismus* are avoided on all levels. Instead, 'xenophobia' has been preferred to describe the same phenomena. Yet, the phenomena are largely the same, and the consequences for the discriminated are the same.

Anthropology has performed a tremendous amount of work on critiquing the essentialization of cultural differences, yet this effort has not substantially changed public opinion and public consciousness. While anthropologists continue to point out that the "world is much more complicated and complex than presented in the media" (and possibly by others) (see, e.g., Ferguson, 2006), cultural identity is still very frequently treated as fixed and irreducible, and biological or cultural. Most anthropologists today agree with John Comaroff (1996: p. 166) that there cannot be a universal theory of xenophobia, nationalism, nativism, Islamophobia, or ethnicity per se, "only a theory of history capable of

elucidating the empowered production of difference and identity." If social worlds are constructed differently, that is, if they are relative, they can still be compared through the appropriate canons of comparison while avoiding conflating cultural relativism with moral relativism. Nevertheless, the essentialization or absolutization of cultural differences remains ubiquitous.

Research on the media coverage of 22 July 2011 in Norway, where the ethnic Norwegian terrorist Anders Behring Breivik went on a killing spree at a summer camp of young political activists whom he judged as immigration friendly, resulting in 77 deaths, has drawn attention to another issue in the study of xenophobia and, particularly in this case, Islamophobia. The Breivik case showed the tendency to reduce acts of terror to individual pathologies. The pathologizing comes easily through the association of xenophobia with phobias, but there is nothing 'natural' about most xenophobia. Instead, it is 'naturalized.' Therefore, acts such as Breivik's should not be explained as the outcome of a lone wolf (Boisen and Hervik, 2013). Instead, lone-wolf claims need to be analyzed for their social function and as communicative acts that serve to deflect attention from ideologies that a person such as Breivik also shares, such as the conspiracy of 'Eurabia.' Reducing xenophobia, nativism, and racism to individual pathologies is taking these phenomena out of history, deflecting attention from immediate circumstances and structural conditions.

Unlike xenophobia, nativism has primarily been studied as a phenomenon in North America. Thus, the ideas that allowed for nativism to appear in this particular context are related to the history of a 'settler nation.' In this new nation, 'native-born Protestants' regarded newcomer Catholics as a threat to their 'original' values and 'society's norms' and therefore opposed immigration harshly. Hans-Georg Betz (2007) argues that the concept of nativism can be applied to a European context, particularly in relation to the anti-Islamic arguments recently used by radical and extreme-right parties and movements. At least two mutually reinforcing anti-Islamic arguments are set forth here: Islam is an alien religion, fundamentally incompatible with Western Europe's secular values and way of life; and, given its 'totalitarian' claims and aspirations, Islam is a fundamental threat to individual freedom and liberal democracy. As in nineteenth-century American nativism, a people or civilization is seen as "inherently different to the members of another civilization"; something within Islam and in the nature of Muslim people, this argument goes, makes them inherently more prone to pursue their objectives with violent means (Betz, 2007: p. 47).

Betz's introduction of the concept of nativism to the European context raises the issue of what units comprise the 'native' group at hand. We can conceptualize it as religious, national, ethnic, or racial. Or, since these are also political entities, what ideological group, or what belief system, do the nativists claim to be their out-group adversary? Are these units recognized as standing in a relationship of superiority and inferiority? What kinds of fissures can be discerned among them?

Fatima El-Tayeb (2011) has found, for instance, that in Europe a racialized understanding of proper Europeanness and Westerners in a nativist manner continues to exclude certain migrants and their descendants. Rather than restricting the term 'migrant' to that first generation who physically migrated across borders, the racialized European understanding represents the second and third generations as 'migrants' as well, although they are in effect minority citizens. These processes of externalization (or social exclusion), where second-, third-, and fourth-generation citizens are continuously racialized and ethnicized as foreign and inferior, now threaten to further polarize and radicalize society. Also, citizens who are seen as sympathizers of unwanted migrants and the 'annoying difference' they represent are also being placed in question.

The new perception of xenophobia or nativism is to a high degree associated with the emergence and drastic increase of Islamophobia, particularly in Europe but also in North America. A closer look at this development can help us further clarify the terms 'xenophobia' and 'nativism.' In attempts to reduce these to a core of negative attitudes or beliefs, it may be argued that following terrorist attacks, it is predictable if not obvious that Islamophobia would rise. This, however, does not happen mechanically. It is helped along by organized agents, who are willing to capture the situation and use the mediatization of society to produce moral panics and a politics of fear, in order to support their organizations and initiatives.

Islamophobia

In its own terms, Islamophobia is yet another concept that refers to 'xenophobic' reactions to the Islamic faith and to Muslims. The xenophobic association would yield a 'fear of Islam,' but it is in reality a xeno-hostility – a hostility toward Islam and Muslims. The notion of 'phobia' as a social phobia does not seem to be present. So, whereas xenophobia embraces both fear and hatred, Islamophobia is a more aggressive and predatory entity (Appadurai, 2006).

Initially, Islamophobia was defined as 'an unfounded hostility toward Islam, and therefore fear or dislike of all or most Muslims' (The Trust Commission on British Muslims and Islamophobia, 2004 (originally written in 1997)). The term gained its prevalence in a public discourse after the 9/11 attacks in 2001, but it also spread through the discussions of the UK Runnymede Trust Report on Islamophobia in 1997, and the Danish Muhammad cartoon conflict in 2005–06. However, there is no full agreement on what 'Islamophobia' refers to. During the Danish Muhammad cartoon crisis, after a Danish newspaper had published cartoons of the Prophet Muhammad, the Free Speech society and its organized anti-Islamic sympathizers grew strong, having both network relations and shared core values with the neoconservatives on the east coast of the United States (Hervik, 2008). In the wake of the Breivik murders in Norway, it has become clear that Islamophobia was organized in the so-called Counter-Jihad movement, which has likewise extended economically and ideologically to North America. That movement as well as the Free Speech Society subscribes to the notion of the Eurabia conspiracy, which was first formulated by author Oriana Fallaci and the historian Bat Ye'or in 2004 and 2005 (see Strømmen and Indregard, 2012: p. 23). According to this conspiracy, Europe is being taken over by Muslims in collaboration with their European multiculturalist and left-wing intellectual collaborators. These Muslims will introduce shari'a law and turn Europe into a caliphate. Immigration, collaboration, and

high rates of fertility are the means to do this (Bangstad, 2013). Accordingly, the understanding of the conspiracy is constructed both as a populist criticism of the elite and as a racialization of Muslims. Conspiracy theorizing, however, can also have effects beyond the ideological content itself and the communication about elite betrayals: it serves as an operational spur to urgent, extraordinary, or violent action (van Buuren, 2013).

The term 'Islamophobia' itself is rather misleading: it literally refers to the fear of a religion, while in fact it is a fear of Muslims and a hostility legitimized because they adhere to Islam. The term indicates religious discrimination, but intolerance toward racial, class, and cultural identity is also closely related to it. In this way, Islamophobia does not contain one simple meaning but, rather, encompasses different discourses that define the sociopolitical situation of Muslim minorities in Europe (Cesari et al., 2006: p. 8). Christopher Allen (2010: p. 195) describes Islamophobia not as a 'phobia' as such, but rather as a form of governmentality, or an ideology that reduces the meaning of Islam and Muslims to an anti-other jeopardizing neoliberal Western values.

Matti Bunzl has argued that Islamophobia and anti-Semitism hold two separate historic origins and are therefore two phenomena that have little in common. Anti-Semitism arose strongly in the nineteenth century with the development of the idea of "race, which gave the Jews an immutable biological destiny. Jews could never belong to the national German community, no matter their strivings for cultural assimilation" (Bunzl, 2005: p. 502). But critics see it differently, and obviously both anti-Semitism and anti-Islamic racism can be found earlier than Bunzl had found it (Smith, 1996; Gardell, 2011). Gingrich (2005) directs our attention to Edward Said's work on Orientalism to show that Islamophobia was present much earlier than the recent emergence suggested in Bunzl's claim. He also reminds us about Frontier Orientalism, which considered Austria one of the historical conflict zones (besides Spain, Italy, Russia, and the Balkan countries). This is not missed by the extremist-right anti-Islamic networks in Europe, particularly the 'Gates of Vienna' blog, to which terrorist Anders Behring Breivik was much attracted, as well as the blog of Peder Are Nøstvold Jensen (aka Fjordman), Breivik's biggest single inspiration. The 'Gates of Vienna' blog bears the slogan: "At the siege of Vienna in 1683 Islam seemed poised to overrun Christian Europe. We are in a new phase of a very old war."

In response to Bunzl, John Bowen (2005) insists that Islamophobia has been well known in France since the Algerian War (1954–62) and deeply rooted in Algerian colonization (from 1830 onward); it persists in reactions to continuing violence in North Africa, Lebanon, and elsewhere. These attitudes, he argues, involve a mix of condescension toward Islam, postwar hatreds, and ordinary racism.

Against defining Islamophobia merely as an attitude, as "indiscriminate negative attitudes or emotions directed at Islam or Muslims" (Bleich, 2011: p. 1581), Brodkin (2005), in her reaction to Bunzl's argument, insists that Islamophobia is seen as state supported and also supported by social movements (2005). Nina Glick Schiller (2005) also criticizes Bunzl for his thin material and for neglecting the doctrine of War on Terror announced by President G.W. Bush following the 9/11 attacks. Her argument is that Islamophobia is not, as Bunzl claims, replacing ideas of race but is a variant of racialized thinking. The very rhetoric and the attitudes she encounters in Europe are based on ideas of immutable cultural difference that now use 'culture' for 'race' only as old wine in new bottles.

Analysts of Islamophobia have attempted to distinguish between hostility to Islam and to Muslims. Whereas the past may have seen Islam as the faith of the enemy, today the target is different: "The attack is now against not Islam as a faith but Muslims as a people" (Halliday, 1999: p. 898). But the distinction between hatred of Islam and hatred of Muslims is hard to sustain. Intolerance of Muslim prayers, clothes, eating habits, living arrangements, and so on, often supported by state policies, reveals an attack on cultural identity. In this perspective, Islamophobia does not necessarily indicate a secular form of discrimination but, rather, a social–political discourse of anti-Muslim sentiments and intolerance (Erdenir, 2010: p. 29). Since 9/11, Muslims have increasingly become stigmatized, a metonym of all kinds of troubles in Western societies. Not only are they seen as a financial burden and blamed for crime, violence, and fundamentalism, but also they embody a challenge to the neoliberal state and the values associated with it. As Evans (2011: pp. 1752–1753) puts it: "What makes Islam exceptional in the eyes of the neoliberal order is its vast membership, its potential as a global mass movements, and its distinctive and complex tradition of religious belief, political ideology, social norms, world outlook, and philosophical method." Islamophobia is a xenophobic reaction, but it is also much more. The ideology of a Eurabian threat and the compendium by the terrorist Breivik are two of the sources among many that show what John Esposito (2011: p. xxvi) has called "the nexus of Islamophobia, multiculturalism, and Muslim-West relations," with nationalism and Eurocentrism as the two nativist nodes. Islamophobia does not necessarily indicate religious ideology and anti-Muslim discourse; rather, it is based on cultural incompatibility. Muslim cultural identity ends up being the enemy, or rather one of the enemies. This notion of cultural incompatibility alludes to the 'new racism' ideology, which will be discussed in section Cultural Incompatibility – The New Racism Discourse and includes confrontational stances and attacks on multiculturalists and others.

Cultural Incompatibility – The New Racism Discourse

Like all emotions, xenophobic feelings must be studied in context and therefore also be seen through a constructionist lens that includes the social evaluation of the rights to a given feeling (Lutz and Abu-Lughod, 1990). In recent years, the growth of anti-Islam sentiments has yielded a claim that xenophobia, besides being chosen instead of the 'reprehensible' racism, is increasingly regarded as justifiable and legitimate. In the aftermath of the Danish Muhammad conflict, interviewees in Hervik's (2011) study agreed that xenophobia has become legitimate in Danish society, due to the association of Islam with terrorism in Danish news media coverage; a large section of Danish society now considered Muslim values and Danish values as incompatible. This tendency to naturalize xenophobia can be seen as a consequence of the high percentage of Europeans (ranging

from 40 to 60%), who see greater interaction with Muslims as a threat (Betz and Meret, 2009).

The idea that xenophobic attitudes and reactions are 'natural' is one of the key features of the neoracism (cultural racism and cultural fundamentalism) that arose in the United Kingdom (Barker, 1981) and the Nouveau Droit that arose in France (Taguieff, 1988) in the late 1970s and early 1980s. In a new rhetorical shift, the political right now acknowledges the equality and equal rights of people of different cultures, but at the same time it emphasizes the 'natural' belonging of people to certain places in the world. Liisa Malkki (1992: p. 27) has found such naturalization in people's unreflective use of plant metaphors and kinship talk when they discuss identity and belonging: "People often thought of themselves as being rooted in place and as deriving their identity from that rootedness." This supports the 'national order of things' as the 'natural order of things.' The theory of human nature embedded in neoracism, then, is that people can be found in the 'wrong' places, where they do not belong 'naturally' (as a consequence of being 'uprooted'); therefore, deriving from this notion, xenophobic reactions will be the expected and natural consequence of human nature (Barker, 1981; Stolcke, 1995). Out of this understanding of xenophobia as a natural reaction, antimigration springs as a nativist necessity and a right to defend 'one's culture,' while either legitimizing racism or denying that cultural and political self-defense can be racist. In the Nordic context, in the last 15 years, people have increasingly believed that some differences were so great that they could not be overcome. The widely different newcomers could never be integrated and should therefore be 'sent home' (Hervik, 2011).

New racism in Britain has drawn its strength from the defense of a mythic British or English way of life in the light of political and social crises, and what could also be seen as nativism, since it promotes an in-group of established citizens. An in-group or 'we-group' promotes itself through its opposite, which it negates. This group does its identity work by opposing the 'cultural other,' or 'itself as the other's other,' which, as I argued, lies behind Huntington's (1996) narrative of 'clashes of civilizations.' The attention to religious (and at the same time cultural) artifacts such as the Muslim headscarf, or to physical characteristics, becomes an indicator of cultural racism. The 'other' is culturally incompatible.

Bunzl (2005) has raised important questions about anti-Semitism and Islamophobia in both a diachronic and a synchronic comparative perspective. His focus and material are not so broad, and his research was conducted before such mega-events as the Muhammad cartoon conflict and 22/7 in Norway. For his part, Bleich (2011), a political scientist, comes out strongly calling for tight definitions, so that he can do comparative analysis and work with causes. However, Barth (1999) has convincingly argued that comparison has come to deal less with actual phenomena and more with definitions, conceptualizations, and texts. This is the shortcoming of Bleich as well, who does not include the level of practice – with all its complexities – or the integral support of institutions.

What kind of revisions would Bleich, Bunzl, and the commentators have made if they had been able to include what happened in Norway on 22 July 2011 and the Muhammad cartoon crisis? Research into these events has revealed that Islamophobia and nativism are not the only things that were at stake. Feminists, multiculturalists, and cultural Marxists are equally as much the objects of hatred as the Muslims. The identification of some of these other enemies comes out loud and clear in the 'cultural war of values' strategy in Danish politics (Hervik, forthcoming) and in radical right-wing political programs. They also combine with a populist discourse, where rhetoric of war serves to naturalize violence and the slip from politics into war, such as war and terror and defending Europe against the emergence of Eurabia by any means. The terrorist Breivik killed young multiculturalists and cosmopolitans at their summer camp in Norway, but the collective categories were dealt with ideologically in writing long before that. They were categories selected as adversaries in the 'war,' and they were 'elected' or 'selected' for elimination (Balibar, 2005).

In the systems of belief underlying the actions of Breivik and the network of extremists and radicals who share most of his values, xenophobia, nativism, and Islamophobia combine with violent and/or ideological attacks of adversaries. In future research, much thicker contextualization is needed in anthropological research on how these manifestations of Islamophobia relate to anti-Semitism (not least among people who are not Muslims or Jewish), and how Islamophobia in people's reasoning relates to antimulticulturalism, antifeminism, left wingers, and labelings of the 'political correct.' We need to theorize the intrinsic relations of combined forms of exclusionary ideologies, discriminatory practices, and identification patterns.

Xenophobia: Social Psychological Aspects

Margarita Sanchez-Mazas, Université de Genève, Genève, Switzerland

Abstract

Xenophobia refers to a fear of the stranger that has taken on diverse forms throughout history and is conceptualized according to different theoretical approaches. Often confounded with racism in modern times, the concept of xenophobia is rooted in universal fears of the unfamiliar, but also in specific historical traditions and regulations regarding the place devoted to outsiders within host societies. With the rise of the nation-state and the development of migration, xenophobia depicts immigrants, asylum seekers, or populations of immigrant descent as posing a material or identity threat to nationals.

Very often the word xenophobia is simply used as a synonym of prejudice – with no clear distinction with the term of racism. Racism is a form of prejudice toward individuals or groups based on the socially constructed notion of 'race', which defines social categories on the basis of differentiating phenotypical markers such as skin color. In contrast, coming from the Greek words *xenos* = stranger and *phobos* = fear, xenophobia denotes a hostility toward the stranger perceived as a threat. However, the notion of stranger is ambiguous, ranging from total otherness to the foreigner next door.

The Greek root *xeno*s may evoke the stranger as a general category, referring to the uncommon or the unfamiliar, as well as a political dimension that, rather than a universal psychological reaction to extraneity, is primarily concerned with rules and regulations that codify access to a territory and demarcate the civic body from the outsiders. Therefore, xenophobia may be conceptualized at different levels of analysis, depending both on the targeted stranger and the theoretical frame of reference. Nevertheless, the core notion of threat seems to be consistently associated with the phenomenon and is present in most theoretical approaches of its social psychological roots. Indeed, reactions to the stranger have been addressed both on their positive side as welcoming behaviors toward the outsider as a guest or partner for exchange, and on the negative side as an aversion toward the outsider as a menace. However, the fundamental ambivalence attached to the figure of the stranger (Simmel, 1908/1984) fades away in the case of xenophobia. This is unambiguously a response to the alleged dangers a given society faces when confronted with someone who is not 'one of us'.

Hence, xenophobia is not simply an attempt to demarcate oneself from the other. Underlying the phenomenon, particular classifications allow to distinguish members of the community from all those who belong to the outside world (as were the barbarians for the Greeks or in modern times citizens of other nations) or from those who become, temporarily or permanently, and under a variety of forms, 'strangers from the inside' (as were the Wogs for the Greeks or are the contemporary immigrants). These 'foreigners living among us' can be considered as the typical targets of xenophobia. The relationship with them may vary considerably, between acceptance and rejection. Xenophobia is an explicit hostility against those who are considered as intruders, usurpers, or vectors of disease.

As a social psychological phenomenon, this hostility has often been understood either as a decontextualized fear of otherness, or as a form of prejudice against an out-group somewhat confounded with racism. Yet, the more recent forms of enmity against immigrants, which have developed under the very name of xenophobia within national contexts recruiting 'guest workers', have received less research attention. This may be due to the focus of Western social psychology on the study of universal psychological processes. However, these can hardly account for the genuine xenophobic reactions that arise when members of a receiving society are entitled with formal rights and prerogatives that are denied to the members of an incoming group. Recent research has addressed anti-immigrant attitudes in a variety of ways, reflecting the increasing complexity of immigration issues that are concerned with a larger array of targets in the current context of globalization. Within this turn, it becomes difficult to disentangle xenophobia, as a fear of the stranger, from a large variety of responses to the presence and arrival of people whose presumed difference from national majorities evokes material as well as value, cultural and symbolic threats.

The Fear of the Other

Throughout history, outsiders have been associated with risks. Unclean foods, unusual hygienic customs, contagion, or epidemic spread stand as potential dangers motivating avoidance of intergroup encounters. The Jewish people, for instance, have experienced persecution on the basis of their alleged propagation of disease from the Middle Ages, where they were blamed for poisoning the water, to the contemporary era in which anti-Semitic propaganda has likened them to nonhuman carriers of germs and infections. A number of models link the recurrent and widespread disease-related reactions to outsiders to adaptive behaviors bearing safeguard and protection for the group against potential harmful contacts. The evolutionary approach attempts to explain how contemporary psychological experiences, and in particular xenophobic attitudes, may reflect ancestral adaptive mechanisms eliciting affective and behavioral reactions aimed at keeping the stranger at a distance (Faulkner et al., 2004). While evolutionary models identify perceived risk of becoming ill as

 http://dx.doi.org/10.1016/B978-0-08-097086-8.24031-2

a central feature, another line of thought draws upon psychodynamic theory for understanding blaming responses as a means to protect the identity of the self by denying one's own vulnerability to illness and linking health and safety risks to the 'other' (Joffe, 1999).

Either at a collective or at an individual level, several social psychological models have addressed fundamental processes underlying perceived threats – whose fear of disease is but one significant case in point – and eliciting anxiety, stigmatization, and prejudice (Stangor and Crandall, 2000). Yet, along these lines, research has stressed a universal and decontextualized version of the stranger, equating it with the transhistorical figure of the Other. Moreover, recent accounts from genetic theory derive in-group favoritism and out-group derogation from the operation of genes and hormones (Dawkins, 2006).

While these borrowings from other scientific domains, such as biology, may contribute to an understanding of an indiscriminate and panhuman hatred of strangers, it fails to grasp the peculiar social, political, and symbolic underpinnings of contemporary xenophobia. These are more accurately accounted for by classic social psychological models, even though, most often, the phenomenon remains confounded with neighboring notions such as prejudice, discrimination, or outgroup derogation.

The Societal Context of Xenophobia

Xenophobia should be situated in its wider societal context. According to Scheffer (2011), the cycle of interethnic relations following immigration generally comprises three steps: avoidance, conflict, and accommodation. "On arrival, migrants tend to keep themselves to themselves, partly as a result of the attitude of avoidance they detect in the society around them. In the years that follow, migrants and their children struggle to claim a place for themselves in the new country, and this leads to rivalry and strife. The question of how everyone can live together becomes unavoidable. If a satisfactory answer is found, the descendants of the original migrants will be absorbed more or less smoothly into society" (Scheffer, 2011: p. 6). Xenophobia can be seen as a symptom of the avoidance and/or conflict steps, and interpreted as reactions of host community members facing societal changes often experienced as threatening. Migrants often experience this perception of threat as well, which may lead some of them to withdraw in their own community. This withdrawal then contributes to strengthen host community members' mistrust.

With the transformations of migration flows, the arrival of immigrants and asylum seekers from more distant non-Western regions, but also with the settling down of reunited families and the increase in the numbers of second or third generation residents born or grown up in their families' host country, discourses about immigrants tend to include a series of themes related to values, culture, or habits. Migration is not only more diverse in terms of cultural origins, but groups of migrants tend to assert their cultural identity through struggles for recognition involving ostensible signs or demands for cultural or religious arrangements (Sanchez-Mazas, 2004). Furthermore, former societal divisions along political lines during the cold war have given way to a framing of antagonisms in cultural terms, for example through the notion of 'clash of civilizations' (Huntington, 1996). The turning of xenophobia into more radicalized forms of hostility toward the culturally different foreigners jeopardizes not only harmonious multicultural relations within nation-states, but also the construction of a cosmopolitan worldwide society.

However, these themes do not replace, but rather merge with more traditional arguments evolving around the actual or alleged foreign status of the immigrant offspring. This combination of delegitimation registers has important implications in the recent evolution of xenophobia toward more complex and combined forms of anti-immigrant attitudes. The fact that the populations of immigrant descent are still viewed as foreign regardless of their formal citizenship allows a wider range of anti-immigrant prejudices compared to prejudice against indigenous ethnic minorities. Thus, in France, access to formal citizenship has not prevented relegation of 'youngsters from the suburbs' to a second-class citizenship, hence feeding among them feelings of denial of recognition, sometimes giving rise to violent outbursts. In addition, anti-immigration discourses include both blatant and subtle expressions of prejudice (Pettigrew and Meertens, 1995), the latter being often associated with apparently rational arguments about 'tolerance threshold', scarcity of jobs, or welfare abuse that legitimize the expression of 'politically incorrect' opinions against them. Hence, the stranger, now reconstructed as an Other reluctant to integrate, and therefore as a menace to Western culture, is the target of rhetorical positions against 'foreign overpopulation', 'invasion', or 'flood' (i.e., the expression 'migration tsunami' used by French far-right leader Jean-Marie Le Pen).

Classical xenophobic themes involving notions of foreign invasion and overgrowth have gained momentum during the last decades, as asylum policy has been placed on the political agendas of Western nations. Official discourses concerned with national sovereignty, State control over borders, and antiterrorist policy after 11 September 2001 have targeted immigrants and asylum seekers, in such a way that threats posed by incoming refugees and other immigrants were associated with fears regarding domestic security. Concerns with the volume of asylum seekers have been addressed through expeditious processing of applications, tight restrictions upon the right to work, removal of support, or detention for failed asylum seekers. The representation of the refugees as claiming for asylum on a fraudulent basis, searching for illegal work, or being engaged into criminal activities such as drug dealing and prostitution, represents a renewed vision of the undeserving and unwanted foreigner (Sayad, 1991). In addition, the liberalization of Western economies has produced a category of precarious illegal workers who can easily be marked out as stealing jobs or lowering wage rates. Hence, nowadays, rejected asylum seekers are the preferred target of xenophobic discourses. These discourses lie at the core of right-wing populist politicians' strategies for conquering power.

Realistic Threats

Several major social psychological theories addressing the psychological roots of prejudice propose key concepts that

might be highly relevant for the study of xenophobia. Thus, a structural approach conceptualizes intergroup prejudice as reflecting the modalities of intergroup relations that can be framed in terms of competition over scarce resources or asymmetrical economic power. This *Realistic Conflict Theory* (Sherif, 1967) assumes that intergroup conflict, but also intergroup cooperation, stem from material interests that provide the infrastructure of reciprocal representations. However, images not only evolve according to the transformations of the nature of interactions, they also actively contribute to the unfolding and the justification of these interactions. The xenophobic rhetoric depicting immigrants as taking advantage of jobs, housing, or welfare opportunities originates from the perceived realistic threat foreign workers or foreign unemployed pose to nationals. Empirical research dealing with xenophobia against 'guest workers' in Switzerland showed that negative attitudes toward foreign people went hand in hand with the perception of intergroup relations in terms of negative interdependence between groups. That is, these interactions were perceived as a competitive relationship between Swiss nationals and foreigners, in a zero-sum game where 'what the other group gains, my group loses' (Mugny et al., 1991). This competitive zero-sum belief has also been identified as a mediator in the relationship between social dominance orientation – the individual preference for hierarchy within social systems – and negative attitudes toward immigrants (Esses et al., 1998).

Concern over material threats may be a relevant criterion for differentiating xenophobia from other types of prejudice primarily based on feelings of in-group superiority. The impact of alleged economic menaces on attitudes toward immigrants has been found both in Europe (Pereira et al., 2010) and North America (Esses et al., 1998). Indeed, arguments blaming foreign populations for benefitting from undue advantages at the expense of nationals are pervasive, particularly in those countries where immigrants, deprived of citizen rights, nonetheless benefit from the welfare system. Thus, people who see themselves and their national group as relatively disadvantaged in comparison with immigrants experience resentful feelings. This kind of reaction, typical of xenophobia, perfectly fits the assumptions of *Relative Deprivation Theory*. Because, unlike *Realistic Conflict Theory*, it emphasizes the subjective evaluation of this disadvantaged comparison (Pettigrew et al., 2008), this perspective helps explain the prevalence of xenophobia under different objective circumstances as well as the sensitivity of public opinion to anti-immigration stances about the foreign 'profiteer'.

Identity Threats

Social Identity Theory complements the *Realistic Conflict Theory* by adding a symbolic dimension tapping people's identities and belief systems (Tajfel and Turner, 1986). It is based on the notion that social identities are part of the self-concept, and that people are motivated to derive a clear and positive image of their social identities through comparisons with other social categories. The explanation of prejudice, including prejudice against immigrants, is often derived from *Social Identity Theory* predictions (Esses et al., 2005). Symbolic motives underlie intergroup attitudes and behaviors and account for the tendency to favor one's own group because it serves and secures its members' sense of identity. Thus, this model clarifies some observed discrepancies in receiving societies between interpersonal relations with out-group members and political stances or voting behavior. Hence, people may support xenophobic political parties while at the same time describe friendly relationships with immigrants. Social identity theory may explain this gap according to the notion that attitudes and behaviors held at an intergroup level are driven by social identity motives – i.e., maintain or acquire a positive social identity as a group member – that differ from interindividual motives, such as personal attraction.

The combined effects of perceived material and symbolic threats are very much plausible in the development of xenophobic attitudes. But perception that their national, subnational, or supranational identity is threatened by divergent social practices, values, or cultural arrangements introduced by immigrants may be sufficient to trigger prejudice against them among majority-group members. Muslims, in particular, are portrayed as posing such a value threat, as shown by examples of xenophobic political parties condemning the use of the Muslim scarf, the presence of minarets, or the selling of halal meat. Indeed, Velasco Gonzalez et al. (2008) found that prejudice against Muslim immigrants among Dutch adolescents was predicted by symbolic threats and negative stereotypes, but not realistic threats.

Perception of the values of immigrants as being incompatible with those of the receiving society implies the vision of nationals as a homogeneous group sharing common values (Esses et al., 2005). The view that immigrants undermine national values suggests that xenophobia correlates with nationalism. However, nationalism has proved to be a determinant of anti-immigration attitudes only to the extent that national identification is framed in ethnic – rather than civic or political – terms that is, with an emphasis put on ancestral values, shared culture, and blood ties (Pehrson et al., 2009). Since nations vary in the importance they attribute to different dimensions of national identity and citizenship (e.g., the German vs the French models and the corresponding jus sanguinis and jus solis), different approaches to the presence of people of foreign origin are to be distinguished, ranging from cultural assimilation – imposing strong cultural obligations – to multiculturalism – promoting culture maintenance among immigrant minorities. Besides, identification at other levels than the nation could also inspire xenophobia. For example, a study conducted in Belgium showed that identification with Europe, rather than national identification, positively correlated with a tendency to wish there were fewer foreigners in Belgium (Licata et al., 2011).

Xenophobia and Attitudes toward Immigration Issues

Xenophobia can be expressed through informal prejudice against individuals in day-to-day interactions. However, it can also inspire political position-taking regarding immigration issues and policies (Licata et al., 2011). Citizens of receiving countries may adopt different attitudes toward entry criteria set for immigrants, which define who can enter and live in the

in-group territory. Entry criteria can either be based on category membership (ascribed criteria), such as nationality or religion, or on individual merit (acquired criteria), such as education or professional skills. Green (2009) showed, across 20 European countries, that citizens of countries with a poor economic situation (i.e., experiencing realistic threat) expressed stronger support for the use of ascribed immigration criteria than citizens of wealthier countries. She also showed that individual perceived threat (realistic and symbolic) was more predictive of support for acquired criteria in wealthy than in poor countries. This suggests that xenophobic attitudes toward foreigners are mainly based on a social category distinction inspired by economic threat in poorer countries, whereas they tend to be based on a meritocratic ideology and pressure to normative conformity on individual immigrants in wealthier nations.

The way different categories of immigrants are named and represented in public discourse and the media, particularly on the moral dimension, heavily weighs on xenophobic attitudes. Esses et al. (2008) showed that negative attitudes toward refugees and the Canadian refugee policy were influenced by representations of refugees as immoral (not respecting the asylum procedure, cheating, etc.). As a case in point, the expression 'illegal immigrants' or 'undocumented' immigrants have different connotations. 'Illegal' contains an accusation of criminality and, through internal attributions, portrays the immigrant as active and guilty. In contrast, 'undocumented' refers to bureaucratic procedures. Suggesting external attributions, it presents the immigrant as a passive victim of the system. Not surprisingly, in the USA, different segments of the population tend to use the two expressions: 'illegal' is often used in legislative debates, whereas 'undocumented' is often used by immigrant rights groups (Deaux, 2008).

Of particular relevance is the framing of immigration as a personal choice or as a constraint, which affects attitudes toward integration policies. Verkuyten (2006) showed that presenting immigration as a personal choice, rather than as 'lack of choice', led to more negative attitudes toward multiculturalism in the Netherlands. This held true both for work-related immigrants (Moroccans or Turks) and for refugees and asylum seekers.

Research conducted in Germany also showed that negative attitudes toward immigrants – both blatant and subtle forms of prejudice – predicted the endorsement of ideologies of assimilation or segregation (versus integration) of immigrants (Zick et al., 2001). Conversely, Ward and Masgoret (2008) showed in New Zealand that both endorsing a multicultural ideology and having contacts with immigrants decreased perception of threat. A lower perceived threat was then associated with more positive attitudes toward immigrants, which, in turn, predicted more endorsement of positive immigration policies (higher number and greater diversity of immigrants).

Studies conducted in Québec and in California (Bourhis et al., 2010) showed that respondents who endorsed more restrictive acculturation orientations toward immigrants (assimilationism, segregationism, or exclusionism) had more conflictual relationships with them than those who favored more welcoming orientations. Studies carried out in Québec further revealed that more restrictive acculturation orientations were endorsed with respect to devalued – visible minorities – but not with valued immigrants – Christian White immigrants from Europe.

Reducing Xenophobia

Different strategies have been proposed for reducing prejudice. They are generally based on the social psychological theories that have been mobilized to identify its causes and can be applied to xenophobic instances of prejudice. However, most research on prejudice reduction has been conducted in laboratories with artificial groups (Paluck and Green, 2009), or focused on racist prejudice against Black people, and cannot be blindly extrapolated to xenophobia. There exist, however, interesting exceptions.

Research assessing Allport's (1954) contact hypothesis has consistently confirmed that intergroup contact reduces prejudice, provided it takes place on an equal footing, involves cooperation (positive interdependence), allows for the development of close relationships, and receives institutional support. For example, a longitudinal study with school students from three European countries – Germany, Belgium, and England – showed that contact between host majority members and immigrant minorities' members had a positive effect on majority members' subsequent attitudes toward immigrants (Binder et al., 2009). But the reverse relation was also true: prejudice reduced opportunities for contact. These effects were strengthened if immigrant friends were seen as typical members of their group. In addition, reduction in intergroup anxiety mediated this effect. Interestingly, however, this positive effect of contact was not found among immigrant participants.

Building on *Social Identity Theory*, scholars have explored the potentially beneficial effects of different solutions based on social categorization strategies (Paluck and Green, 2009): The recategorization strategy aims at reducing prejudice by decreasing the salience of a social identity while emphasizing a superordinate level of identification that includes both the in-group and the out-group; the crossed categorization strategy is based on the idea that making members of both groups aware that they share a belonging to a third group should improve their relations; finally, the dual identification strategy tries to make a superordinate category salient, while at the same time maintaining identification with the subgroup. Each strategy was found to yield significant reduction in prejudice, although mainly in laboratory settings using artificial groups and with prejudice being measured as in-group bias. A study conducted in Australia by Nickerson and Louis (2008) in real settings brought support for the dual identification strategy. It showed that attitudes toward asylum seekers were the most positive among participants who both identified with their nation and as human beings.

Prejudice against foreigners has also been investigated in the framework of models addressing social norms and conformity. Conformity to group norms proves to depend on perceived in-group threat and on the extent to which the norm provides an appropriate answer to such a threat. Falomir-Pichastor et al. (2004) observed that Swiss nationals conformed to an antidiscrimination in-group norm (i.e., they reduced discrimination against foreigners) when the

out-group was perceived as nonthreatening (i.e., when foreigners were not perceived as taking jobs nor increasing nationals' unemployment). However, the same norm did not obtain any influence, and a counterconformity effect even tended to appear, when the out-group was perceived as threatening. Hence, adhering to antidiscrimination norms endorsed by the in-group tends to decrease prejudice, except when immigrants are perceived as threatening economic or symbolic interests.

Xenophobia vs Xenophilia

Xenophobia and racism are difficult to oppose since these phenomena are subject to transformations and often become confused. Interestingly, however, unlike racism and other related notions, xenophobia has an antonym: Xenophilia, meaning sympathy for the stranger. Thus, xenophobia can be considered as the opposite of hospitality. In a variety of historical situations, foreigners have been marked out as not belonging to the political community. Yet, embodying different characters – the merchant, the pilgrim, the beggar, the fairground stallholder – they held a designed place among local citizens and natives. According to the roman distinction between *urbs* – the material town – and *civitas* – the civic city – they brought novelty to the former while being excluded from the latter. While xenophobia reflects the refusal to incorporate the foreigner as a citizen, it develops in the framework of a bond or even interdependence between outsiders and the host society.

Indeed, whereas the total stranger triggers fears and hostile reactions, the foreigner can become familiar when his or her otherness is mastered through categorization processes, social practices, and institutional controls that define his or her status within a given community. Besides antagonism, the relationship with the stranger is also open to alliance and reciprocity, sometimes represented through rituals or recognition signs. In premodern times, for example, the traveler receiving hospitality would give his host half of a piece of clay, a *symbolon*, and keep the other half for himself, in such a way that, when the host traveled in turn, he could be recognized abroad as a guest rather than a stranger.

Nowadays, the rising of xenophobia conceals opposing trends in most Western societies toward the development of multiculturalism, the adoption of antidiscrimination laws and diverse forms of support to immigrants and asylum seekers claiming for their rights. Opposing xenophobia through institutional devices, volunteer support, or political mobilization contributes to shape today's complex and contradictory forms of the relationships with foreigners. Contemporary manifestations of xenophilia involve political and ideological positions as well as individual and collective behaviors, which still realize nowadays some of the fundamental dimensions of human experience, such as persons mobility, intergroup contact, mutual social influence, and integration of novelty.

Abstract

In considering the effects of globalization and urbanization in many parts of the world, anthropologists' attention has been drawn to the implications of these processes for a large but often marginalized global cohort of young people. To address these circumstances, ethnographic studies in this field have also expanded from a primary focus on peer cultures to include more concerted accounts of intergenerational relations as well. Contemporary research in anthropology is therefore likely to situate young people within a complex set of networks, processes, and activities, including a more varied treatment of the relationship between youth and culture.

For much of the history of anthropology, as for other social sciences, scholarly attention toward youth was shaped by a paradigm of socialization and a focus on adolescence as a life cycle stage. Since the mid-1990s, this orientation has shifted to include both a more concerted focus on young people in their own right as well as a more diversified set of approaches. This shift reflected the conjuncture of several different influences: the earlier seminal work of what has been called the Birmingham School, whose studies of youth subcultures helped to establish cultural studies as an interdisciplinary field of interest; the rethinking of notions of culture and power within anthropology; and increasing attention to the effects of globalization and urbanization on an expanding global cohort of young people.

As the number of studies focusing on young people has increased, the parameters of ethnographic studies in this field have also expanded from a primary focus on peer cultures to include more concerted accounts of intergenerational relations as well. Contemporary research in anthropology is therefore likely to situate young people within a complex range of relations, processes, and activities. As a result, the relationship between youth and culture has come to be treated in more varied ways including attention to the role of young people as cultural producers as well as to the involvement of a broader range of agents in the construction of age and generational categories and distinctions.

Defining Youth

The range of persons anthropologists include in the category of youths has often varied depending on the cultural context in which this position is being defined and on what question the researcher is asking in respect to this field. In a rare early example of a systematic ethnographic focus on youths, during the 1920s Margaret Mead conducted research centering on a group of girls, ranging in age between 10 and 20 years, who were residing in three villages on the Samoan island of Tau (Mead, 1928/1968). In carrying out this research, Mead was concerned to answer the question of what 'coming of age' meant in Samoa and how this differed from the experience of growing up in the USA. She claimed that unlike the emphasis on storm and stress, which then (and has since) dominated American characterizations of adolescence, growing up in Samoa was a simple, easy matter, a process which involved no special conflicts or dramatic transitions. Beyond the obvious signs of physical maturation, she suggested that there were few differences between Samoan girls still approaching puberty, those who were just passing through this transition, and those already several years beyond it. Given this emphasis, it is hardly surprising that Mead was not concerned with defining the boundaries of adolescence too precisely or distinguishing it sharply from either childhood or young adulthood.

In contrast, Alice Schlegel and Herbert Barry's (1991) much later survey of adolescence in ethnographic accounts of 186 nonindustrial societies was more expressly directed at delimiting this stage cross-culturally. Schlegel and Barry argued that while the social duration of adolescence varied cross-culturally and between genders, it was universally recognized as a social stage of the life cycle and tended to fall between the ages of 11 and 17 or so. When social adulthood was delayed far beyond puberty, a further stage intervened between adolescence and adulthood, a stage that Schlegel and Barry called 'youth.' While adolescence was universal, the stage of youth was only recognized in a minority of societies.

However, this distinction between adolescence and youth as two distinct social stages is not otherwise common in the anthropological literature on youth culture. More often this literature is likely to draw attention to the ambiguity of notions of childhood and youth. In part, these ambiguities reflect

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12168-3

variations in the construction of the life course in shifts across both space and time. But in part, these ambiguities also reflect analytical orientations. For example, a cross-cultural collection of articles on youth cultures edited by Vered Amit-Talai and Helena Wulff (1995) included groups ranging in age between 10 and 30 years with considerable variation in the scope of autonomy and social responsibilities represented among them. However, this collection, unlike Schlegel and Barry's or Margaret Mead's studies, was not directed at defining youth (or adolescence) as a stage of human development. Rather it was concerned with the ways in which young people creatively engage with, are affected by, and in turn help to shape the statuses, images, products, styles, and orientations identified, sometimes very broadly, with youth. In short, it was concerned with the experiences and attributions of youth rather than when and how youths become adults.

While later studies have been much more interested in processes of 'coming of age' they have noted that the movement from childhood to youth to adulthood is ambiguous, situationally defined and often contested (Durham, 2007: p. 118). So collections of case studies are still likely to include the wide range of ages that appeared in the Amit-Talai and Wulff volume. In order to avoid taking for granted definitions of youth that may fit into particular historical moments or places, Deborah Durham (2004: p. 592) adapts a linguistic term to introduce the concept of youth as a "social shifter," a concept that has both an indexical and referential function. Treated in this way, the concept of youth does not so much define an age grade as raise questions about the relationships between different age categories and statuses. However, Karen Tranberg Hansen (2008: p. 5) cautions against the frequent slippage between terms like child and youth that occurs in the burgeoning literature on young people as well as in the delineation of age categories by international development and nongovernmental organizations. The "difference between these terms matters," Hansen argues (Ibid).

The Cross-Disciplinary Antecedents of Youth Culture Studies

While Margaret Mead was very successful as a popularizer of anthropology, she was not equally successful in provoking fellow anthropologists to continue her focus on adolescents. For many years following Mead's work in Samoa, youths largely remained marginal figures in the anthropological record. Concerted interest in this field was much more evident in other social science disciplines than it was in anthropology. During the 1930s, a little over a decade after Mead's initial research in Samoa, the sociologist William Foote Whtye began participant observation fieldwork in the North End of Boston. Whyte's (1943/1981) classic ethnographic study of the organization of peer relations among second-generation young Italian men in a 'slum area' exerted a seminal influence primarily on the development of US urban studies. Yet it was and remains one of the most thorough and sympathetic portraits of youth street life ever produced, effectively countering the notion of social disorganization that had dominated the US sociological literature on inner cities until that point. Not long after Whyte's study was published, the concept of youth culture appears to have been introduced by another American sociologist, Talcott Parsons (1942/1964) and was later taken up more systematically by James Coleman (1961) to denote the circumscription of American youth peer interaction.

It was, however, the work of British cultural theorists during the 1970s and early 1980s which did most to develop youth culture as a central field of research on class, subculture, and consumption. During this period, the Center for Contemporary Cultural Studies (CCCS) at the University of Birmingham, sometimes referred to as the 'Birmingham School,' launched an ambitious collaborative study of British youth subcultures (Hall and Jefferson, 1976). For the CCCS scholars, youth appeared to offer a special vantage point from which to consider the more general dislocation and fragmentation of the British working class as the structure of Britain's system of production, labor force, income distribution, and lifestyles was transformed over the course of the post–World War II period. The emergence of a variety of highly stylized British youth subcultures (i.e., punks, mods, skinheads) appeared to crystallize the growing importance of mass culture, consumption, and leisure practices as bases for increasingly fragmented working class identities. The gaze of the CCCS was self-consciously selective, focusing on young British nonconforming white working class males. The larger population of 'ordinary' working class youths who accommodated to rather than visibly resisted institutional controls, middle-class youths, and girls, with some notable exceptions, were not accorded similar attention, gaps which were well noted by later critics. The members of the 'Birmingham School' were also criticized for reading ideological undertones of class resistance and consciousness into what sometimes appeared to be fairly trivial instances of adolescent rebellion. In spite of an emphasis on case studies, the CCCS published work was notably slim in empirical findings. Here again, there was a notable exception in Paul Willis' (1977/1981) ethnography, Learning to Labour, which followed a group of boys, the 'lads,' through their last year of high school and onto the industrial shop floor. Yet, in spite of these limitations, the Birmingham School's focus on popular culture, consumption practices, resistance and cultural agency, and their attention to youth as a nexus for broader social change, continue to resonate in research on youth culture both within anthropology as well as in other disciplines.

Youth Culture: A Move Away from Socialization

The mid-1990s is often identified as a turning point in attention to youth within anthropology. But this turn really encompasses two shifts rather than one. The first turn marked a determined move away from socialization approaches. In volumes such as Vered Amit-Talai and Helena Wulff's (1995) Youth Cultures: A Cross-Cultural Perspective as well as in volumes dealing with a rethinking of approaches to childhood (James and Prout, 1990; Stephens, 1995), socialization approaches were criticized for entailing less of a focus on youths than on the adults they will eventually become or the

adults attempting to direct and socialize them. Instead an argument was made for attention to youth agency, which was interpreted as an insistence on respecting the capacity of juveniles to be active agents creatively shaping their environment even as they contend with a variety of legal, political, economic, and social constraints imposed on them by virtue of their age and liminal status.

The emphasis on agency emerged within the context of a broader reorientation of anthropology away from the notion of unitary and enduring cultural formations that was more common in Mead's day to a conception of culture that could more easily accommodate internal diversity, fragmentation, and transience. This made it easier for anthropologists to be comfortable with a notion of youth as eliciting specific kinds of knowledge and cultural competence that are different from rather than incomplete versions of adult cultures. It also rendered more persuasive the claim that youth cultures can have broader analytical and social significance even when they are highly ephemeral and situationally specific. During the 1980s and 1990s, critical reappraisals of the conventions of ethnographic accounts, in particular of the ways in which the textual authority exercised by anthropologists can silence or distort the perspectives of the people they are studying, provided a broader context for a reconsideration of the ways in which ethnographic representations had effaced the presence and experiences of children and youths. In a cogent illustration of the dialectical nature of intellectual exchange, an essay by George Marcus (1986) in a volume that was particularly influential in this broader anthropological reassessment, focused on Paul Willis' seminal CCCS ethnographic study of working class boys in school. In turn, volumes of this kind and the critical introspection they prompted influenced subsequent anthropological studies and representations of both children and youth.

But in spite of their conceptual aspirations, the legacy of the Birmingham School as well as the emphasis on agency that was introduced within anthropological work on this subject all too often combined to produce a narrowed emphasis on one domain of young people's lives, their relations with age peers. On the one hand, the Birmingham School tended to treat youth culture as a particular form of working class subculture manifested in peer interactions standing "in opposition to other cultural forms [which] took shape most fully in the domain of leisure beyond the institutional controls exerted in more formal realms" (Amit, 2001: p. 147). On the other hand to the extent that the later 1990s insistence on youth agency sought to compensate for socialization approaches that were criticized as being too adult centered, it too often tended to emphasize peer interactions among children and youths (Ibid). As a result, while the efflorescence of interest in youth during the 1990s did produce a flurry of ethnographic studies, many of these were focused on youth peer relations and popular culture (for example, Pilkington, 1994; Thornton, 1995; Alexander, 1996; Schade-Poulson, 1999). While such an interest is not necessarily problematic in and of itself, when it begins to crowd out consideration of other involvements and relationships it portends three possible consequences. First, as Jennifer Cole has noted, this approach "runs the risk of fetishizing and reifying the category of youth" (2004: p. 573). Second, it decontextualizes the lives of young people, painting a "picture of youth as an entity, which is socially and culturally detached from the surrounding world" (Christiansen et al., 2006: p. 16). Third, because it focuses on such a narrow range of youthful activities, it also threatens the marginalization of the study of youth within anthropology and related disciplines (Amit, 2001). Ironically, therefore, a field of research that had been inspired and shaped by the Birmingham School's orientation toward youth as a vantage point from which to consider broader societal transformations was increasingly circumscribed as a narrow domain of inquiry separate from these larger contexts.

Youth, Generation, and Context

In the 2000s, this narrowed treatment of youth cultural production was challenged by a second shift in this field, which featured a re-embedding of young people's lives across a variety of contexts. A major impetus for this reorientation came from anthropological studies conducted in various African locales. In Africa, anthropologists were encountering a situation in which young people predominated numerically but were often marginalized in terms of access to employment, education, health, and social services as well as political and economic influence (De Boeck and Honwana, 2005). This marginalization occurred within the context of processes of globalization including IMF-imposed structural adjustment programs, the influx of international aid, and the creation of free trade zones (Christiansen et al., 2006; De Boeck and Honwana, 2005; Moyer, 2004; Cole, 2004). The resulting shrinkage in the state, decline in social services, and rising unemployment (Moyer, 2004: p. 120) had an especially severe impact on youths even as they were also targeted as potential consumers (Cole, 2004: p. 573). But the exclusions of young people were further heightened by elite hierarchies predicated on generational divisions. As Jean and John Comaroff (2005: p. 24) have pointed out, these generational divisions are social and political rather than chronological. Indeed as Meyer Fortes argued in 1984, chronological age and generational categories "may be wildly out of sync" (Fortes as cited in Durham, 2004: p. 591). Nicholas Argenti further notes that "African political hierarchies are said to be gerontocratic not because men (and to some extent women) accumulate power as a function of growing old but, on the contrary, because they can only grow old to the extent that they have successfully accumulated wealth and power" (2007: p. 8).

Caught between the workings of globalization and gerontocratic hierarchies, young people in many African locales have found previous avenues for mobility blocked. Whereas schooling was once considered a means of upward mobility, even young people who have acquired educational credentials can no longer count on gaining preferred white collar jobs but are instead facing un- or underemployment (Durham, 2004: p. 601; Moyer, 2004; Cole, 2004: p. 576; Argenti, 2007: pp. 8–9). The result has been that many young people are not able to acquire the means to establish their own households,

assume responsibility for dependents or exert politicoeconomic influence within more extended family or communal networks. Moreover, without the capacity to assume these responsibilities and authorities, they are not able to achieve a secure adulthood. They are, in short, 'stuck' in the categorical status of youth.

In their interpretations of these kinds of tensions, anthropologists have turned to some older work on issues of generational distinctions and transmission such as Karl Mannheim's (1952) essay on 'The Problem of Generation.' In doing so, they have emphasized the *relational* nature of generational and life course categories, the "specific circumstance that generate and emphasize one generational category over another" (Christiansen et al., 2006: p. 10). Such an approach insists that "youth cannot be analytically separated from the network of social relations in which they are embedded" (Cole, 2004: p. 585) and these social relations include families, elders, and juniors as much as generational peers.

If the marginalization of young people in Africa has been sufficiently acute to make generation an inescapably "dominant line of cleavage" on this continent (Comaroff and Comaroff, 1999: p. 284), many of the processes of exclusion to which anthropologists have drawn attention in this region, are also reflected in the circumstances of youths in other locales as well. Thus in a comparison of young people in Recife (Brazil), Hanoi (Vietnam), and Lusaka (Zambia), Karen Tranberg Hansen has noted that these cities do not afford many of their young inhabitants a decent livelihood (2008: p. 3). Young men studying in Meerut College in North India find themselves remaining in education for long periods after they have tried and failed to get the middle-class jobs (Jeffrey, 2010). Like their contemporaries in many African countries, these Indian students had aspired to positions in government bureaucracies, a form of work that they had grown up viewing as secure and well paid (Jeffrey, 2010: p. 471) but a shortage of employment and a dramatic increase in the numbers of young, educated people has meant that most of them will not be able to secure these kinds of white collar positions. Craig notes that similar kinds of developments have been observed in other postcolonial settings (2010: p. 467) while in their introduction to a volume examining the circumstances of young men in different parts of the world, Vered Amit and Noel Dyck (2012: pp. 11–12) point out that high levels of youth unemployment have extended across *all* world labor markets even as evidence has also accumulated about the uncertain or limited rewards of educational qualifications in many parts of the globe. Hence Karen Tranberg Hansen argues that these circumstances may well be contributing to a "convergence of global youth experiences" (2008: p. 4) in spite of sometimes-stark differences in the respective age profiles of different regions. Amit and Dyck observe that these developments have rendered the efforts of many young people "to conform to dominant and pervasive orthodoxies a double-edged sword: on the one hand, if they do not acquire any or much formal schooling, they risk being viewed as failures; on the other hand, if they do attend school but do not succeed in achieving the kind of 'good jobs' that this education is assumed to enable, then they are also likely to be viewed as failing" (2012: p. 14).

According to Jean and John Comaroff, a global feature of the contemporary world "is a sense of crisis surrounding the predicament of juveniles" (2005: p. 20). Viewed in these terms, the circumstances of young people cannot be slotted away into a segregated domain of activities. Instead, anthropologists working in many different parts of the world increasingly view the contradictions exposed in the construction of youth as a historical and relational category (Durham, 2000: p. 114) as well as in the positioning and experiences of the people attributed this status, as poignantly revealing of the more general – global, national, and local – contexts within which they live.

Extending and Diversifying the Study of Youth

There is a sense in which youth studies in anthropology have returned to the original ambition of the Birmingham School of treating youth as a vantage point from which to examine general social transformations. But more recent efforts seem to have expanded the scope of this standpoint to encompass a much wider range of youth involvements, relationships, and cultural constructions. But if one conceptual emphasis is simply replaced by another, for example if a stress on agency is simply supplanted by one on generation, then the scope of youth studies will once again, be more limited than it needs to be. Fortunately, there are indications that a dynamic interchange is occurring between previously distinct approaches. Taking "age itself as an analytic" (Cole and Durham, 2007: p. 14) allows scholars to deconstruct and re-examine some of the truisms that are often associated with childhood or youth, for example the notion that 'children are the future' (Cole and Durham, 2008: p. 21). In critically examining the construction of different age, life course and generational categories, youth as a status, distinction or set of practices, is treated relationally and contextually. Hence much of the reinvigoration of the classic concept of generations has not rejected the importance of attention to agency but has sought to critically interrogate it within different spheres and activities (Durham, 2000).

Furthermore, elements of this kind of reinvigoration and interchange have appeared across a wide range of youth studies. Thus recent studies by Brent Luvaas of young fashion entrepreneurs and 'indie pop' bands in Indonesia consider the development of youth styles in respect to processes of globalization (Luvaas, 2009, 2010). If Cole and Durham are concerned to pick apart truisms about the future, Luvaas is equally concerned to question the tendency to automatically associate youthful stylistic appropriations with resistance to imported commodities and tastes. Some socialization or developmental approaches have recently featured notions of agency by extending concepts of "active subjectivity" to children as well as adults (Kontopodis and Newnham, 2011: p. 72) or have noted the impact of globalization and urbanization on the 'reorganization of lifecourse cultural models' (Worthman, 2011: p. 432).

Today, considerations of youth that focus variously on style, socialization, agency, generation, life course, groupings, and practices have not necessarily merged but they are much more likely to overlap as the specific questions being posed and processes being examined require. One of the effects of the diversification and extension of the ways in which youth is being

approached is the deconstruction of a concept like 'youth culture.' Youths are certainly being considered as cultural producers but youth is as likely to be approached as a cultural construction in and of itself. The relationship between youth and culture thus raises a wide scope of questions rather than an already demarcated field of investigation.

Abstract

The study of youth culture has a long history in sociology and the social sciences. The pioneering Chicago School of Sociology was especially concerned with young people as they engaged in delinquency and deviance. Youth culture was enabled by social changes like the extension of public schooling and the growth of consumer culture, and during the 1960s young people would become powerful agents of political and cultural change. The upheavals of the 1960s proved to be a pivotal turning point that transformed sociological approaches to youth culture. Subsequent studies have emphasized the symbolic acts of resistance perpetrated by an increasingly diverse range of subcultures.

The notion of a distinct youth culture and the problems of young people have been enduring topics of study among social scientists. The sociology of youth culture developed through the empirical investigation of issues specific to young people, initially in the psychosocial concept of adolescence, later in studies of juvenile delinquency and deviance, and finally in the analysis of subcultures and their symbolic forms of resistance. The construction of 'youth' as an intermediary phase of the life cycle and a source of identity is inextricably linked to social factors, particularly the extension of schooling and the growth of consumer culture. The rise of youth culture thus parallels the international hegemony of American culture and the mass media, which became most firmly entrenched after World War II but was clearly discernable by the 1920s. The power of youth culture reached its zenith during the 1960s through the hippie counterculture and the New Left, and by the end of the decade young people in many parts of the world had become politically involved as students in social movements. After the 1960s, many scholars began to assess youth culture in terms of its capacity to resist power and create social change. The ethnographic study of subcultures and various forms of youth culture continues to be a vital interdisciplinary field for contemporary scholars.

Adolescence and the Origins of Youth Culture

The notion of adolescence was initially developed by the pioneering psychologist G. Stanley Hall. In a two-volume work published in 1904, Hall defined adolescence as a stage of life between childhood and adulthood, one that social institutions should preserve as a period of self-exploration. The experience of adolescence was shaped by a mixture of biological and sociological processes. Adolescence was characterized by emotional volatility and conflict, which Hall called 'storm-and-stress.' Hall had been strongly influenced by the Romantic writers of the eighteenth century, including Rousseau and Goethe, the latter of whom had written the classic tale of young heartbreak and suicide in *The Sorrows of Young Werther*. Hall argued that the turbulence of adolescence was especially acute among American youth, who were confronted with the lure of vice in the industrializing cities while being deprived of the rites of passage that marked the transition to adulthood in preindustrial societies. Hall advocated for extended years of schooling and other institutional reforms which would allow adolescents to explore themselves while delaying their entry into adult society (Arnett, 1999).

This 'in-between' phase of the life cycle was enabled and extended as a result of the expansion of public schooling for older youths during the early decades of the twentieth century (Nasaw, 1979). Extended schooling concentrated teenaged boys and girls together in institutions, which, unlike the military, could not control all of their behavior and were not typically segregated by sex. High school and college students began to create an age-specific culture centered on their schools, mainly through extracurricular activities and clubs, such as after-school dances, glee clubs and choruses, student government, and school newspapers. At American colleges during the 1920s, the Greek system of fraternities and sororities prevailed as the dominant social grouping with exclusive hierarchies of status and prestige; these quickly became linked to collegiate sports and especially the growing popularity of college football (Fass, 1977). Competition for status among high school and college students created pressure for social conformity along with heightened alertness toward shifts in fashion and fads. These social anxieties about keeping up with peers could be exploited by commercial forces and advertisers who were just beginning to recognize the value of young people as consumers. Youth culture and consumerism would be closely intertwined from this time on, with consumption becoming the primary means of either conforming to peer groups ('fitting in') or competing for the status of nonconformist hipness ('standing out').

While the extension of schooling helped create youth culture by sequestering age groups, youth culture was also developing among working-class youth outside of schools, in the city's streets and spaces of entertainment. In American cities, millions of young people from immigrant families would form a vanguard of cultural change, discarding the ethnic culture and traditions in favor of a modern, Americanized identity shaped by consumer culture and the mass media. Department stores, dance halls, and amusement parks were among the places of commercialized leisure where working-class youth converged and created a cultural style

distinctive to their age. These urban spaces of amusement and consumption presented young working-class women, in particular, with unprecedented opportunities to evade the strictures of patriarchy imposed in their immigrant households (Peiss, 1986). Above all, movie theaters would prove to be the most popular gathering place for young people, as nearly half of all American adolescents were going to the movies at least once a week in 1922. Beginning in the 1920s, the movie studios competed for this coveted audience by releasing different films with 'youth' in their title; one of the most popular and provocative was *Flaming Youth* (1923), which included a 'skinny-dipping' scene of naked bodies shot in silhouette (Savage, 2008).

The segregation of young people into a distinct social group enabled the formation of subcultures characterized by symbolic resistance to social norms. Flappers were a pioneering subculture, which emerged in the 1920s, composed of young women who defied the dominant forms of femininity through their distinctive fashion and association with the hedonism of the 'Jazz Age.' The flapper's signature was a short, bobbed hairstyle, a modern and androgynous alternative to the long, flowing hairstyles that prevailed among Victorian women. The flappers were also associated with shorter skirts and the heavier use of cosmetics, stylistic markers that suggested more assertive attitudes toward sexuality and overall greater independence of self. Like all the other youthful subcultures, which followed, the flappers would be exposed to the larger public through the mass media, who invariably represented them through a prism of sensationalistic anxieties about changing gender roles and sexual behavior. Nonetheless, the 1920s was a decade of major changes among young people who were increasingly engaged in a range of premarital sexual activities and had begun the practice of going on dates without chaperones. Though sensationalized, the images of flappers in the mass media – dancing boisterously to jazz, smoking, and drinking in public, etc. – were a reflection of significant changes in gender roles and sexual norms occurring in the 1920s (Dumenil, 1995).

Deviance and Juvenile Delinquency: Sociology and the Chicago School

In the nineteenth century, authorities of various stripes constructed the social category of juvenile delinquency in connection with a host of social problems arising from urbanization and immigration. This diagnosis of delinquency informed the groundbreaking research of the Chicago School of Sociology beginning in the 1920s, as delinquents and gangs were studied through ethnographic methods and analytically connected to the social ecology of urban life. As the city of Chicago emerged as a focal point for movements toward social reform, the concern for young people led to the creation of the Juvenile Protection Association (JPA), founded by Jane Addams and her colleagues in 1901. Over the next several decades, the JPA supported numerous studies of social problems surrounding urban youth, including prostitution, drug use, child labor, poverty, and racism. The collection of data about young people and the push for social reform were connected with the larger Progressive Movement, particularly those reformers known as the Child Savers who had a crucial role in inventing and defining the category of juvenile delinquency (Platt, 1969). Sociologists at the University of Chicago later inherited these depictions of delinquency, and their studies of youth and gangs would link them to the larger problems of social disorganization in industrial cities.

The Chicago School of Sociology produced its pioneering studies through methodologies that mixed observation and documentation, interviews and oral history, and the study of official statistics. These studies were informed by a broader perspective on urbanization, developed by Robert Park and Ernest W. Burgess, which considered the city as a sort of ecological system, where people competed for resources, adapted to their environment, and formed a kind of equilibrium in their social lives. This social ecology model of urbanization was applied in the groundbreaking studies of gangs by Thrasher (1927) and juvenile delinquency by Shaw and McKay (1942). Thrasher maintained that the attachment to territory was paramount for gang formation, as illustrated by the fact that gangs were ethnically homogenous in homogenous neighborhoods but could also be ethnically mixed if they formed in mixed neighborhoods. He observed that gangs tended to develop from the playgroups of children, and that their bonds of loyalty to one another became stronger as adults and authorities expressed their disapproval. Shaw and McKay built upon the ecological model by stressing the effects of social disorganization with respect to juvenile delinquency, which they saw as symptomatic of the weakening of social bonds in urban neighborhoods. Consistent with Burgess' model of how urbanization develops in zones of concentric circles, Shaw and McKay demonstrated that neighborhoods nearest to the city's center tended to have the highest rates of delinquency, regardless of which ethnic group inhabited them at a given time.

Beyond the Chicago School, youth became a central topic of concern for sociologists during the 1930s, and Talcott Parsons was the first to examine youth culture in an article published in 1942 (Brake, 1985). Parsons (1942) maintained that youth culture was defined by its reversal of the values of adult society, namely hard work and conformity, in favor of consumption, leisure, and mild hedonism. The 'glamour girls,' 'swell guys,' and 'good companions' who were the most esteemed individuals within youth culture were characterized by physical attractiveness, athletic success, and popularity among peers. While Parsons noted the ways in which youth culture inverted mainstream values, he confidently asserted that it had an important function in facilitating the transition from childhood to the social roles of adulthood. The youth culture, which Parsons analyzed, clearly revolved around high schools, rather than city streets and neighborhoods, and he neglected to examine class differences within youth culture. Hollingshead's (1949) ethnographic study of high schools revealed how social class, mediated by family and neighborhood, shaped the status hierarchies of adolescent cliques. Others, including Coleman (1961), downplayed the role of class in favor of a pluralist model, which maintained that youths had access to diverse sources of social status, with Coleman adding that all these status groups within youth culture were united by an antagonism to the educational values of the school.

Juvenile delinquency would reemerge as a volatile issue in American society during the 1950s, and again sociologists

produced a series of studies that documented and analyzed these social problems associated with youth. In 1952, public concern about juvenile delinquency led the US Children's Bureau to create the Special Juvenile Delinquency Project. The US Senate Subcommittee on Juvenile Delinquency was formed in 1953, and the following year it held hearings (led by Sen. Estes Kefauver) to investigate whether comic books were negatively influencing young people and provoking delinquent behavior. These hearings in the Senate expressed growing concerns about the influence of the mass media and commercial entertainment over young people, from comic books to movies to popular music (Gilbert, 1986). In turn, movie studios appealed to the fascination of the public in general and young people in particular with gangs and juvenile delinquency, prompting the controversial releases of films including *The Wild One*, *Blackboard Jungle*, and *Rebel Without a Cause*. Such imagery also played an important role in the evolution of rock 'n' roll in the 1950s, and it was here that young people's attraction toward the defiance of the working-class delinquent would become most apparent.

The sociological analysis of juvenile delinquency centered on the concept of anomie, which Robert Merton (1938) broadened beyond its original formulation in the works of Durkheim. Whereas Durkheim generally defined anomie as the disconnection of individuals from society, Merton revised it to describe the disaffection of those who lack opportunities for upward mobility. Merton's conception of anomie would be fundamental to the development of his strain theory of deviance. As the ideologies of meritocracy and egalitarianism suggested that opportunity was equally available to all, the realities of inequality and social reproduction frustrated those who could not advance through the legitimate institutions of mainstream society. Merton developed a typology of deviance based on the motives of deviant actors with respect to 'cultural goals' and 'institutionalized means.' Other sociologists later added that understanding the motivation was not sufficient for a full explanation of deviance, as one must also explain how people learn to engage in deviant behavior through their association with other deviants (Cloward and Ohlin, 1960).

Albert K. Cohen (1955) built upon Merton's strain theory of anomie and deviance in a study of Chicago-area gangs. Cohen argued that gangs develop among young people who share a similar 'problem of adjustment' in a society divided by class. Gangs tended to form among working-class youth who could not or would not adjust to middle-class values, particularly the middle-class values that promote education as a path to upward mobility. If delinquent, working-class boys faced a 'problem of adjustment,' then the gang or delinquent subculture represented a 'collective solution' by upholding alternative norms and criteria of status. While rejecting schooling, deferred gratification, and other middle-class norms, delinquents formed subcultures that valued masculine toughness, group loyalty, and the ability to negotiate violence. Gangs and delinquent subcultures depend on regular social interaction and an intense degree of group solidarity, which serve to insulate them from the negative judgments of mainstream society. Typically, their values and norms directly invert those of mainstream society, to the extent that "the delinquent's conduct is right by the standards of his subculture, precisely because it is wrong by the norms of the larger culture" (1955: p. 28).

Counterculture and Student Movements in the 1960s

The 1960s were a pivotal moment when young people brought about significant changes to the political systems and cultural norms of societies in many parts of the world. The student activism of the New Left and a more all-encompassing counterculture grew in the US during the 1960s, and oppositional youth culture and student movements would become international phenomena during the riotous events of 1968 and the turbulent years that followed. In the US, college students played a leading role in the Civil Rights Movement during the early 1960s, and opposition to the Vietnam War later in the decade incited the student movement's expansion on an international scale. The counterculture's influence proved to be more diffuse, as an antiauthoritarian style and sensibility spread among young people in search of personal liberation. Although the individualism of the counterculture often conflicted with the collective efforts of the New Left, the youthful culture of opposition also significantly shaped the theatrical tactics and egalitarian ethos of those movements for social change. While the link to radical politics was largely severed after the 1960s, the antinomian culture, which developed during that decade, particularly its music, would exert a lasting influence on various youth subcultures that followed.

The number of students enrolled at institutions of higher education multiplied at its greatest rate during the 1960s. Competition with the Soviet Union led the US government to increase federal spending for higher education through the passage of the National Defense Education Act of 1958. A substantial increase in the birth rate following the end of World War II – America's 'baby boom' – meant that massive numbers of students would enroll at colleges and universities beginning in the mid-1960s. The baby boom generation was poised to benefit from US economic and geopolitical dominance in the decades after World War II, with the ranks of the white middle class swelling and enjoying an unprecedented growth in their standard of living. The growing numbers of young people with increasing disposable incomes made them into a coveted demographic for advertisers, the mass media, and the culture industry, which expanded their appeals to an emerging notion of the 'teenage' market, especially through movies and pop music. The baby boom generation was a celebrated product of American prosperity, but in passing through institutions of higher education it was poised to inherit a vertically managed system linking industry, government, and the military with a consumerist lifestyle centered in recently developed suburbs.

Throughout the 1960s, college students would be key actors in movements for social change, with universities often becoming battlegrounds of conflict. African-American students started the sit-in movement that spread through the South in 1960 and led to the formation of the Student Nonviolent Coordinating Committee the following year. Increasing numbers of White students also started to get involved with the Civil Rights Movement in the early 1960s. After issuing its *Port Huron Statement* in 1962, Students for a Democratic Society emerged as the leading radical organization for students concerned with a host of issues, including American foreign policy and nuclear weapons along with the domestic struggle for civil rights and economic equality. Students could also mobilize in

opposition to the repressive organization and bureaucratic impersonality of the university itself, as evident in the Free Speech Movement at the University of California at Berkeley in 1964. With the escalation of the Vietnam War during the second half of the 1960s, college campuses would become contested spaces subject to teach-ins, demonstrations, occupations, walkouts, and strikes. In the late 1960s, youth began to adopt an oppositional form of collective identity, most directly expressed in the popular saying, 'don't trust anyone over 30.'

Students were at the forefront of an international wave of protest, which swept around the world in 1968, involving both capitalist and communist societies. During the Prague Spring, students had a leading role in liberalizing state control over civil society, which lasted until they were crushed by Soviet forces that August. Meanwhile, students joined forces with the working class to nearly topple the French government in May 1968, leaving behind revolutionary graffiti and slogans, which appealed to desire and the imagination. Particularly during the Spring of 1968, numerous incidents of student protest occurred in Spain, Poland, Italy, Yugoslavia, and West Germany, but also in Algeria, Brazil, Japan, and Pakistan; students were key actors in China's Cultural Revolution, and student demonstrations ended with a horrifying massacre by the military in Mexico City (Katsiaficas, 1987). The global New Left distinguished itself from previous generations with its more horizontal style of organization and participation, and within the student movements political protest was closely intertwined with cultural rebellion and personal freedom. Student protest reached its peak in the US during May 1970, in the days following the invasion of Cambodia and the National Guard shootings at Kent State and Jackson State, which prompted students and faculty at more than 500 colleges and universities to go on strike (Katsiaficas, 1987: p. 120).

The youth culture of the 1960s was profoundly shaped by these movements for social change, while in turn the New Left's political radicalism incorporated much of the style and sensibility of the counterculture. Keniston (1968) and Roszak (1969) argued that youthful radicalism and the counterculture were shaped by their opposition to a totally administered society or 'technocracy' where capital, the state, and mass consumption were fundamentally intertwined. College students quickly discovered that higher education served as a crucial link in this chain of institutions. In response, young people upheld the pursuit of freedom and pleasure against the systemic demands for conformity, instrumental rationality, and deferred gratification. The affluence and security enjoyed by the middle class presented many young people with the opportunity to 'drop out' and experiment with the process of developing an identity and searching for authenticity. Advertisers and media sought to profit from the enormous value of young consumers by incorporating some of the imagery, music, and rebellious attitude of the counterculture; appeals to freedom and nonconformity were thus steered toward consumerism (Frank, 1997).

The vanguard of youth culture in the 1960s was the hippie movement, infamous for its collective pursuit of sex, drugs, and rock 'n' roll but otherwise consistent with some enduring American values of individualism (Miller, 1991). The liberalization of sexuality picked up where the 1920s left off, enabled by innovations in birth control but also by the continuing transformation toward a culture of consumption and individual choice. By the end of the 1960s, the mixture of New Left militancy and countercultural open-mindedness had helped spark the women's and gay rights movements. The hippie counterculture used drugs as tools for the expansion of consciousness and perception, not simply among individuals but as a kind of religious sacrament in the practice of communal joy. Most influential of all was the music scene, which evolved from folk to electrified rock yet continued to be a powerful vehicle of protest and the basis for youthful identities. Rock music appropriated not only the sounds of rhythm and blues but also the defiantly 'cool' bravado of urban African-Americans. Rock music soon proved to be ripe for commercial cooptation, and in becoming big business its symbolic acts of rebellion were increasingly severed from movements for social change.

Resistance and Subcultures: The Birmingham School

In the aftermath of the 1960s, scholars began to examine youth cultures in terms of resistance to hegemonic power, defining them as subcultures engaged in symbolic struggles over culture and style. This approach was developed by interdisciplinary scholars at the Centre for Contemporary Cultural Studies at Birmingham University during the 1970s, and has since come to be known as the 'Birmingham School' theory of subcultures. In contrast to the Chicago School, the theoretical point of departure for the Birmingham School was Marxism, and they conceptualized subcultures as expressions of symbolic resistance from working-class youth against the dominant classes. The Birmingham School revised the orthodox Marxism's notion of a determining base and determined superstructure, thus allowing them to theorize that culture could be a relatively autonomous means of resistance instead of just social reproduction. Youth culture disconnected from political radicalism during the 1970s, but the Birmingham School theorized that subcultures continued to represent indirect, symbolic challenges to the hegemonic powers, particularly through style and the use of signs.

Birmingham School scholars argued that the subcultures of working-class youth maintained a complicated relationship with the 'parent culture' of the working class at large. The mainstream parent culture of the working class includes the elements of resistance and hostility to authority, but overall it is more conventional and accommodating to hegemonic society (Hall and Jefferson, 1976). Youth subcultures are never totally separate from this parent culture, as both are responding to the conditions of social life in the working class. A central idea developed by the Birmingham School was that subcultures represent 'imaginary' or 'magical' solutions to these social-structural issues, exemplified in the way that skinheads sought to recover a lost sense of working-class community by adopting a proletarian style (Cohen, 1972). The demolition of older neighborhoods and construction of high-rise housing projects destroyed the fabric of working-class communities, which had come together in street life or spaces like the local pub and the corner store. At the same time,

a conflict of cultural values between 'traditional working-class Puritanism' and a 'hedonistic culture of consumption' had intensified in the years after World War II through the advent of television and mass culture. Cohen argued that the mod subculture reflected working-class parent culture in their argot and rituals, but their dress and music represented the hedonistic image of the consumer: new and modern, colorful and glamorous. Skinheads, on the other hand, reacted against these social changes by trying to defend their ideal of traditional working-class culture against the hedonistic consumption represented by mods and hippies. Skinheads reasserted an image of masculine chauvinism and Puritanism through their signature style, particularly their workboots, suspenders, and cropped hair, all of which represented them as a 'caricature of the model worker.'

Resistance among youth subcultures is a central theme in one of the most influential studies to emerge from the Birmingham School, Paul Willis' *Learning to Labor* (1977). Willis' ethnographic study examined different groups of working-class youth at school, giving special attention to the rebellious 'lads' who were immersed in a culture of opposition against authority, teachers, their conformist peers, and the whole system of education itself. The lads see their school as an institution of social control, and Willis maintains that they reject the dominant ideology that education is a meritocratic means of upward mobility. The lads have also inherited a working-class 'shopfloor culture' in which masculinity is associated with manual labor, while in turn office work and mental labor are seen as effeminate. Willis argues that the resistance among lads in their schools ultimately serves to reproduce their class position as manual laborers. As teenagers, the lads are eager to drop out and get a job, and it is only as they get older that they will realize how much drudgery and exploitation is involved with manual labor. Willis concludes that this is how working-class kids get working-class jobs, as the culture of opposition to school authorities leaves the lads uneducated and unskilled; ironically, their resistance ultimately reproduces class relations.

Written as punks were defiling the cultural order of British society in 1976–77, Dick Hebdige's *Subculture* (1979) was a similar influential study of youthful resistance that also emerged from the Birmingham School. Here again Hebdige argued that subcultures issue an indirect challenge to hegemonic power through their use of signs. Tracing the development of subcultures from the teddy boys to the mods and rockers to the skinheads and punks, Hebdige presents their semiotic forms of stylish resistance in the social context of a breakdown of postwar Britain's liberal consensus. Subcultures take banal objects, like a safety pin, which seem to have no symbolic meaning, and they appropriate those objects to give them new meanings and uses for which they were not intended. Hebdige (1979: p. 90) argued that "subcultures represent 'noise' (as opposed to sound)" and that they serve "not only as a metaphor for potential anarchy 'out there' but as an actual mechanism of semantic disorder: a kind of temporary blockage in the system of representation."

Within the Birmingham School, some feminist scholars challenged the sexist assumptions behind these conceptualizations of subcultures. McRobbie and Garber (1976) critiqued the Birmingham School for their lack of attention to girls and their silence about masculinity in subcultures. At the heart of the problem is the way that subcultures are defined, as they focus on public spaces where boys have greater access rather than the private spaces to which most girls are confined. Families place greater restrictions on girls and those who spend a lot of time with boys in public are likely to get a bad reputation for sexual promiscuity. Yet McRobbie and Garber maintained that girls still participate in the practices of subcultures, like listening to music and using style as a means of self-expression and experimentation, but the difference was that their activities often take place in more private, domestic spaces. McRobbie and Garber labeled this as the 'bedroom culture' of girls, and they argued that it was imperceptible to male ethnographers of subcultures, like Willis and Hebdige, who focused on the activities of boys in public spaces.

Postsubcultures?

More recently, some scholars have suggested that the Birmingham School theory of subcultures is outdated and needs to be replaced. Many have argued that subcultures are less unified and distinct than the Birmingham School suggests, and moreover that the conflict between subcultures and dominant society is not a simple matter of hegemony and resistance. Such critics have nominated terms like 'neotribes' and 'postsubcultures' to supplant the original concept of subcultures (Bennett, 1999; Muggleton and Weinzerl, 2003). A more fluid, diverse notion of subcultures has become necessary as the variety of styles and identities has multiplied and combined into new hybrid forms during the past few decades. Youth cultures have become increasingly fragmented, overlapping, and ephemeral, and the boundaries separating them from mainstream society are less clear than they used to be. Advances in media and communications technologies have facilitated the multiplication of subcultures and their combination into hybrid forms, while niche marketing allows them to be immediately commodified and assimilated into mainstream society.

Other scholars continue to acknowledge the important contributions of the Birmingham School, while maintaining a critical stance, as they utilize the concept of subcultures in their ethnographic studies of youth culture (Haenfler, 2010; Moore, 2010). The increasing variety of subcultures has prompted scholarly studies of hip-hop (Rose, 1994), extreme metal (Kahn-Harris, 2007), straight-edge punk (Haenfler, 2006), club cultures (Thornton, 1995), and goth (Hodkinson, 2002). They have also drawn attention to the role of young women in subcultures, especially female participation in punk (Leblanc, 1999) and the feminist version of DIY punk known as 'riot grrrl' (Kearney, 2006). While media technologies and niche marketing blur the boundaries between subcultures and popular culture, young people continue to construct identities based on authenticity and a sense of collective difference from mainstream society.

Youth Gangs

Abstract

The origins of youth gangs can be traced back to the eighteenth century, but a consensus on gang definitions has never emerged and wide-ranging theories about the nature of gang culture abound. Although some evidence suggests a proliferation of gang violence in many countries outside of the United States, criminologists need to be aware of the way in which media and political influences generate 'gang talkers.' By focusing only on the small minority of prolific gang members who are involved in most of the violence, law enforcement agencies may have more success in preventing the issues from occurring.

Introduction

Youth gangs have been a part of American culture since the eighteenth century, and elements of subcultural issues among youth can be traced back to the nineteenth century in the UK. But, the word 'gang' is often used loosely by those in the media and political circles. Young people living in deprived communities frequently feel that local residents assume youth gatherings and friendship groups are gangs when, in fact, they are not. There is thus confusion about what gangs are among journalists, politicians, and the general public alike.

Where they do exist, gangs are diverse in American and British society, and not all gangs are the same. And defining what actually constitutes a gang can be problematic. Drawing upon those theories which suggest that crime is a social product, this article explores the commonly recognized causes of gang culture, and begins to examine the difficulties associated with defining youth gangs. It examines the diverse ethnic membership of youth gangs in America, and explores some of the differences in those gangs found in the UK as well as providing a brief history of gang culture on both sides of the Atlantic. The role of the media and political rhetoric is examined in terms of the romanticism, mythmaking, and 'moral panics' that can emerge, and potential solutions are examined within the context of focused deterrence strategies being implemented across the USA and (more recently) in Scotland. Implications for future research and law enforcement practice are considered. Following the conclusion, an extensive reference list is provided to assist with further review of the topic.

The Causes and Nature of Gang Culture

In the late nineteenth century, Emile Durkheim argued that a state of normlessness or 'anomie' may occur in the lives of those who become exposed to unlimited socially generated aspirations combined with a lack of realistic opportunities for achieving these goals (Durkheim, 1897/1952). Later, Robert Merton (1938) took these arguments further when he drew attention to the way in which elements of social and cultural structure exert a 'strain' on some people to engage in nonconformist conduct. He argued that 'aberrant conduct' might arise where there is a disassociation between culturally defined aspirations and 'socially structured means' of achieving these goals (Merton, 1938: p. 674). In Merton's view, large sections of the American population found themselves unable to achieve their aspirations through conventional, legitimate means. Accordingly, the disjunction between means and goals led to a propensity for deviation to emerge (see also Deuchar, 2013).

Albert Cohen (1955) subsequently highlighted that the groundwork for violent behavior includes the existence of unresolved tensions and the drifting together of individuals who experience social exclusion (Deuchar, 2013). In order to deal with these issues, Cohen argued that many young people (and young men in particular) may participate in delinquent subcultures. In so doing, it was felt that young people may engage in innovation, whereby conflict and frustration are eliminated by rejecting conventional means of achieving success and by creating alternatives. Alternatively, they may engage in rebellion, where extreme forms of frustration and marginalization lead to attempts to introduce a 'new social order' (Merton, 1938: p. 678).

Since the beginning of the last century, 'gangs' have been the focus of sociological research and have been commonly cited as manifestations of delinquent youth subcultures. Puffer (1912) was one of the earliest authors in the USA to explore the nature of the gang. He described it as a 'play group,' and argued that gang fighting tended to be centered around personal disputes related to the upholding of a 'code of honor' or could be about territorial disputes with other gangs (Puffer, 1912: pp. 67–68). In early work conducted as part of the Chicago School of Sociology, Frederic Thrasher (1927: p. 57) argued that gangs were characterized by behavior such as 'milling,' 'movement through space,' and conflict that results in 'solidarity' and 'attachment to a local territory.'

More recently, Elijah Anderson's (1999: p. 32) pioneering ethnographic study into urban street life in Philadelphia, the USA, highlights that the inclination to violence "springs from the circumstances of life among the ghetto poor – the lack of jobs that pay a living wage, limited basic public services … the stigma of race, the fallout from rampant drug use." Young men who feel disrespected by others out on the street need to avenge their honor, and require 'running buddies' or 'homies'

that can be depended upon to back them up (Anderson, 1999: p. 73).

The Eurogang Project is a thematic network for comparative research on violent youth groups across Europe and the USA. Two of its members, Frank Van Gemert and Mark Fleisher, have argued that most gangs do not actually share the stereotypical characteristics associated with hierarchical ranks and initiation ceremonies. In order to facilitate gang research across borders, the Network has created a generic definition of a gang as being "any durable street-oriented youth group whose involvement in illegal activity is part of its group identity" (Van Gemert and Fleisher, 2005: p. 12). Indeed, Hagedorn (2008) has highlighted that the deindustrialization process across inner-city areas in the USA and the wider world has led to more violence being motivated by economic impulses. However, other evidence suggests that gang culture in the USA has become associated more with issues of disrespect and the norms and narratives of the street, as opposed to purely being linked to drug markets and economic enterprise (Anderson, 1999; Deuchar, 2013).

Consensus of definition with respect to 'gang' culture does not exist today, with criteria varying across jurisdictions. Many researchers have created their own versions of what constitutes a gang (Klein, 1968; Monti, 1993; Van Gemert and Fleisher, 2005). In fact, every organization that comes in contact with gangs has created an operational definition of the term to suit its own needs. Many recognize that there are different patterns of behavior associated with different types of gangs. Although some young gang members earn a living through drug trafficking, sales of illegal weapons, and other criminal activities, others join gangs for noncriminal reasons. For example, a young person may join a neighborhood gang to get protection in their neighborhood; another may join to gain status, respect, or the type of social support he or she would otherwise not receive at home or in the community; and still others may join for the camaraderie. Whatever the reason, gang members in America are as diverse as the gangs themselves.

Emergence and Growth of American Gangs

Although sociological research into gang culture emerged much later, the earliest record of youth gangs in the USA may have been as early as the eighteenth century. Some of these gangs were known as Smith's Vly Gang, the Bowery Boys, the Broadway Boys, and the Long Bridge Boys (Osman, 1992). These gang members were not necessarily criminals who committed violent crimes, although they did fight with rivals. Redfield (1941) believed the first gangs in the USA migrated from Mexico in the nineteenth century after the Mexican Revolution in 1813. It was around this time that the first criminal gangs were formed. These were youth gangs involved in criminal activity, due in part to the economic situation and the population increase in urban areas.

The Irish immigrants were the first to form criminal gangs in New York City in the 1820s. The 1850s saw an increase in gang membership as urban government corruption was rampant. During the early years after the civil war ended, migration patterns increased for industrial centers like New York, Chicago, and Detroit. The Irish, Jewish, and Italian immigrants who came were impoverished and formed gangs based on ethnicity. It was also at this time that drugs were introduced to gang life. The early part of the twentieth century was dominated by economic turmoil. Due to the increase in population of the urban areas and the decline in the economy, the gap between the rich and poor grew. In the 1920s, Thrasher (1927) estimated that there were over 1000 youth gangs operating within Chicago. He argued that the gang provided a sense of refuge and belonging for young men in socially disorganized communities and was a "substitute for what society fails to give…it fills a gap and affords an escape" (Thrasher, 1927: p. 33).

With the growth of immigrant populations, gang culture continued to expand within the USA. In the early 1940s, large numbers of Puerto Ricans entered New York City. This fact, along with a growing African-American population from the south, contributed to the large minority populations in northern cities. While Irish, Italian, Jewish, and other Eastern European ethnic groups were establishing their communities, Puerto Ricans and African-Americans, including strong pockets of black West Indians, became a strong presence. Racial conflict was clear in northern big cities such as Detroit, Michigan, where one of the worst race riots in American history took place in 1943. Groups of white youth gangs roamed the city attacking black citizens (Sheldon et al., 1997). Around the same time in Los Angeles, the Zoot Suit Riots of 1943 were underway. In these riots, white residents and visiting soldiers harassed and beat up young Chicano men who dressed in the popular zoot suit style of clothing (Moore, 1978).

Hagedorn (2008) highlights that the crushing of revolutionary 1960s social movements by the state in Chicago led to gang culture growing stronger. Further, two of the most violent American gangs – the *Crips* and the *Bloods* – were founded in Los Angeles, California, in the late 1960s and largely comprised African-American membership. These gangs were known to be involved in murders, robberies, and drug dealing and had intense rivalry between them. In time, the gangs migrated throughout the USA and members can be found in numerous States and prison populations. The gangs of the 1970s, with greater use of guns, were more lethal in their encounters than previously (Horowitz and Schwartz, 1974). By the 1980s, the urban ghettos became overcrowded and the youth gangs transformed themselves into entrepreneurial organizations with the crack cocaine epidemic of that decade (Sanchez-Jankowski, 1991). Indeed, Hagedorn (2008) argues that, in today's world, the spaces of the prison and the ghetto coincide, and that street gangs often have strong links to prison gangs. He argues that 'many of Chicago's supergangs' were formed behind bars, and that gangs often use prison to advance their interests.

In addition to these insights, Hagedorn (2008: pp. xxiv–xxv) also raises three fundamental issues about gang culture. First, he argues that gangs are not a unique form, but one of many kinds of armed groups that occupy the slums, including ethnic militias, drug posses, vigilantes, and political extremists. Second, gangs are shaped by racial and ethnic oppression as well as poverty: as marginalized ethnic groups have lost their faith in 'progress' due to the continued prevalence of racism, many have turned toward the 'nihilistic power of the gangsta.' And third, we can best overcome the negative impact of gang culture by encouraging 'cultural resistance identities' and linking them to

social movements. Accordingly, it is important to draw upon the positive aspects of gang culture as a means of finding potential solutions to the problem of violence. In so doing, we must also recognize that the issues associated with gangs are ones that stem beyond the confines of the USA.

Gangs in the UK and the Wider World

Even although the phenomenon of the gang was traditionally seen as an exclusively American entity, claims have emerged that gang culture is proliferating in other countries (Hagedorn, 2008; Hallsworth and Young, 2008). For example, there have been reports about an increase in Moroccan youth gangs who are strongly associated with hip-hop music and *gangsta rap* (Van Gemert and Fleisher, 2005); evidence of Pakistani gangs in Oslo that perform criminal acts and where membership is passed on from father to son (Lien, 2005); and gang leaders who are viewed as heroes to young boys in Jamaica, Rio de Janeiro, and Central and South America (Deuchar, 2009). Indeed, Hagedorn (2008) argues that the proliferation of gangs in Africa and Latin America is due to the combined influence of urbanization, immigration, and social marginalization.

In the UK, it has long been recognized that gangs do not exist solely within the context of criminality. In the 1960s, Yablonsky (1967) classified the type of gangs in evidence in inner-city neighborhoods within the UK into several categories. Firstly, there were 'social' gangs, where a certain degree of responsible social interaction may take place. Secondly, 'delinquent' gangs were primarily organized to carry out illegal acts such as burglary and assault for purposes of profit. And, thirdly, he defined 'violent' gangs as those organized around violence as a means of 'self-protection and defense' or to 'channel aggression' (Yablonsky, 1967: p. 174, and see also Deuchar, 2013). Academics associated with the Eurogang network argue that, unlike the USA, youth gangs in the UK have fluid membership and flexible boundaries and are often involved in less criminally oriented activity (Van Gemert and Fleisher, 2005; Klein, 2008).

One city with a long history of violent gang culture is Glasgow in Scotland. The earliest recorded gangs in Glasgow date back to the late nineteenth century, with the emergence of the *Penny Mob*s. Like their New York City counterparts, these gangs were formed following the large-scale Irish migration that resulted from the famines of the mid-nineteenth century. By the early twentieth century, the smaller gangs had converged and the focus of the gang violence was stimulated by the tensions that arose following the Irish settlement and the subsequent founding of the religiously divided Old Firm soccer clubs (Rangers and Celtic FC). The formation of two notorious gangs in the city – the *Billy Boys* (a Protestant gang) and the *Norman Conks* (from Norman Street, where many Roman Catholics lived) characterized the sectarian divisions within the city at the time (Davies, 2007).

During the post–World War II period, the issue of gang culture in the west of Scotland was rarely mentioned in the popular press. However, from 1965 on, an increasing number of articles on juvenile crime began to focus once again on the subject of gangs and violence, and it was reported that Glasgow had the worst gang problem in the UK (Bartie, 2010). Research into Scottish gangs was carried out by James Patrick (1973), whose ethnographic study identified the presence of numerous territorial gangs in Glasgow, which were centered primarily on violence. For young Glasgow boys, the lure of the gang was seen to be driven by the Glasgow culture of 'self-assertion and rebellious independence against authority as a means of attaining masculinity' (Patrick, 1973: p. 170). Today, it has been estimated that Glasgow is home to approximately 170 street gangs, with the vast majority of their activity centered around territorial disputes (Deuchar, 2009). It has long been recognized that the gang provides some young men in Glasgow with a way to "accrue compensatory social capital, and to experience social bonding, status, identity and the expression of a narrowly-defined but widely accepted version of masculinity" (Deuchar, 2009: p. 144). The 'hyper place attachment' found in Glasgow's deprived neighborhoods is driven by lack of opportunities for employment, social stigmatization, and oppression (Kintrea et al., 2011: p. 68). The same type of territorial rivalry has been identified in other communities in England, although some have suggested that the violence found in large inner-city communities in London and Manchester is more closely associated with drug dealing and firearms use as opposed to the territorial knife crime culture found in Glasgow (Stelfox, 1998; Bennett and Holloway, 2004).

Some academics believe that the current interest in gang culture in the UK is attributable to the same type of 'moral panics' that surrounded the emergence of other youth subcultures such as the 'mods and rockers' in the 1960s and the punks in the 1970s. Hallsworth and Young (2008) argue that many of the young people typically labeled as 'gang members' simply do not conceptualize the peer groups with whom they associate as 'gangs.' Some young people may simply regard their peer networks as 'friendship groups' or 'young teams,' while resisting the gang label (Deuchar, 2009: p. 9). Further, Hallsworth (2011: p. 184) highlights that, even if 'gang' members commit offenses it is often "not evident that the offense in question is motivated by 'gang' membership in and of itself." For academics, it is important to move beyond the gang 'gaze.' Street violence, Hallsworth argues, can be normless and unregulated and often lacks a social orientation. In focusing exclusively on American stereotypes of gang culture and violence, he argues that so-called 'gang talkers' lose sight of the wider issues that lead to street violence (Hallsworth and Young, 2008).

The Role of the Media

The media has been developing a biosketch of a gang member since the Zoot Suit Riots of 1943 and using it to keep fear of diversity in the minds of many. The Watts Riots of 1965 gave the media more ammunition for its exaggerated view of a gangster. Thanks to their portrayal, many people today believe that a gang member is a Latino or African-American illiterate youth, who comes from a female-headed household, in an impoverished urban area. American cinema has a long history of gangster movies. From 'West Side Story' to the more hardcore portrayal of criminal street gangsters today, the cinema has literally been a training ground for gang wannabes. Classic movies such as 'The Godfather' give an excellent

example of Thrasher's (1927) evolution of street gangs, rising from neighborhood playgroups and evolving into successful criminal street gangs. From the portrayal of rebelling youth (i.e., 'Rebel Without A Cause,' 'Blackboard Jungle,' 'Wild Ones,' etc.) to star-crossed love (i.e., 'West Side Story') and the hard-core reality of street gangsters (i.e., 'Menace II Society,' '187,' 'Heat,' 'Boyz in the Hood'), the youth of America did not have to look far for gangster role models.

In recent years within the UK, there has been an explosion of films and media reports on gang culture, which have both romanticized and celebrated gang violence. For example, while films like 'Green Street' celebrate violent soccer gangs, the 2010 Peter Mullan directed movie, 'Neds,' romanticizes 1970s gang violence in Glasgow. Ross Kemp, an English actor and journalist, presented a BAFTA award-winning television documentary series on gangs, while another recent documentary fronted by English actors and singers Gary and Martin Kemp claimed that there is more gang violence in Glasgow than in any other part of the UK. As a consequence of this intense media publicity, public perceptions about gang culture and violence are on the increase even while crime rates are falling.

Increased political focus on gang culture has also led to the demonization of young people. For example, following the English riots in 2011, Prime Minister David Cameron launched an 'all-out war on gangs and gang culture,' describing it as a 'criminal disease' that infects streets across the UK (Hallsworth and Brotherton, 2011: p. 3). Criminal gangs were seen to be key players in the riots, while young people were viewed as being 'out of control' (Hallsworth and Brotherton, 2011: p. 2). And yet, it was later found that fewer than 10% of those who participated in the riots outside of London were known to be gang members.

Society, and in particular some media and political forces, has been ready to assign responsibility for brutal acts exclusively to so-called violent gangs. But the reality is that gang members run the spectrum of angels to demons, and very few of those we might describe as gang members are hardcore, violent individuals. Many may hang out in street-oriented social groupings but never participate in violence. Indeed, researchers have found that most are peripherally involved in violence; more important, there is evidence to show that only a tiny percentage of gang members are responsible for the violence. This leads us to conclude that specific strategies need to be adopted that target the violence initiated by a very small number of prolific offenders.

Strategies for Preventing Gang Violence

Over the years, there have been numerous attempts to try and combat youth violence associated with gangs in the USA. Although suppression strategies such as zero tolerance policing have resulted in some positive benefits in cities such as New York, they have also brought with them a reduction in public perceptions of police legitimacy and equity (Burke, 2004). But, in more recent years law enforcement agencies in the USA have adopted strategies associated with focused deterrence and problem-oriented policing (Kennedy, 2009). First used as part of the Boston Ceasefire in the 1990s, these initiatives are based on the fundamental presumption that the majority of serious violence is committed by a small number of individuals who are often organized (to some degree) in groups or gangs. Gang members are compelled to attend offender notification meetings (or 'call-ins') where they are told that, if a violent incident occurs, law enforcement will punish those who commit violence as well as their associates or 'gangs.' But, service and community partners also offer help in the form of social and job services for those who are willing to move away from violence (see Deuchar, 2013).

The principles were used to form the basis of the Cincinnati Initiative to Reduce Violence (CIRV) from 2007 onwards. Recognizing that the majority of the violence within Cincinnati was caused by a small number of individuals, the initiative drew upon a range of stakeholders including political leaders, law enforcement agencies, academics, medical professionals, Street Advocates, social service providers, and community and business leaders. Targeted gang members (who were mostly young African-Americans males in their 20s) were routinely brought into Hamilton County Court as a condition of their probation or parole and exposed to some powerful messages. First, law enforcement officials warned them that the violence must stop, and drew upon a 'pulling levers' approach to ensure that any and all legal resources were brought into play to punish individuals and their associates who continued to involve themselves in violence (Kennedy, 2009; Engel et al., 2013). Second, community voices appealed to the young men to leave violence behind: reformed offenders and mothers of victims provided messages that were both emotive and effective. And, finally, social service providers described the alternatives available to a violent lifestyle and promised streamlined social service assistance to those willing to transition to a prosocial lifestyle (Deuchar, 2013; Engel et al., 2013).

A quantitative evaluation of CIRV found a statistically significant 42% reduction in gang member involved homicides in Cincinnati over a 5-year period (Deuchar, 2013; Engel et al., 2013). In 2008, the initiative was implemented in Glasgow, Scotland, with some adaptations to suit the local gang problems. The majority of those targeted in Glasgow were young white men, with an age range of 14–19 years. In a similar way to the Cincinnati initiative, the Glasgow CIRV aimed to reduce youth violence through a mixture of enforcement and suppression strategies, the offering of services and programs and the moral voice of the community (Deuchar, 2013). In the final evaluation of the Glasgow initiative, there was found to be a 46% reduction in violent crime in the areas where the initiative was deployed. In particular, significant decreases were recorded in the type of behaviors targeted by the program, such as weapon carrying and gang fighting.

Deuchar (2013) highlights that, on both sides of the Atlantic, the CIRV initiative 'complemented and supported offenders' journeys toward desistance' by providing them with positive institutional influences, supportive human relationships, and an opportunity to take on generative activities. The strategies associated with focused deterrence have also been applied in numerous settings across the United States, and the initiatives have consistently led to positive results (NNSC, 2013). In Scotland and the wider UK, there is also an increasingly common focus on adopting a prevention approach to tackling gang violence through partnership working and the need to provide pathways out of violence.

Conclusion

This article has drawn upon theoretical perspectives that suggest that crime is a social product, and identified the way in which classic criminologists have drawn attention to issues of social disorganization, 'anomie' and strain to explain the reasons that some young people may participate in gang violence. It has provided a historical overview of the research that has been conducted into gang culture on both sides of the Atlantic, exploring the relationship with ethnicity and economic decline. The problems associated with gang definitions have been explored, and the motivation and behavior of gang members in and beyond the context of criminality examined. The article has identified the role that the mass media and political rhetoric can play in romanticizing gangs and/or demonizing young people, and has discussed the potential solutions that have been framed around the need to be clear about who the small minority of prolific violent offenders actually are, alongside the potential for early intervention within the context of focused deterrence.

In the twenty-first century, society needs to define the term 'gang,' taking into account the facts that there are different types of gangs ranging from noncriminal to criminal; loosely knit to highly structured; coming from diverse ethnic backgrounds; experiencing different reasons for joining; as well as choice of activities pursued. In spite of the challenges associated with gang definitions, some consensus must be reached. We also need to ensure that researchers, politicians, and the media avoid demonizing and stigmatizing youth, through differentiating between violent gang members and those who simply become attracted to gang culture for innocuous, social reasons. And law enforcement agencies around the world need to take note of the positive outcomes that have emerged from focused deterrence strategies that concentrate their efforts on those who are responsible for most of the violence. By identifying who the really violent gang members are within a specific neighborhood, focusing efforts on providing them with alternatives to violence while avoiding stigmatizing other young people, perhaps we can find a way of building safer, trusting, and supportive communities.

Abstract

Youth geographies are complex and highly dynamic. Young people are everywhere in our social worlds and are a significant part of the social fabric of everyday living. As a subdiscipline of geography, the focus on young people is relatively new but the theoretical and empirical work has developed rapidly and our awareness of what young people are doing, how they are doing what they do, and, importantly, where they are doing it is expanding and deepening. This article provides an insight into aspects of these developments and a particular focus on young people and political, urban and development geographies.

Within academia, young people in the past have tended to be invisible, neglected, or focused on only because of their deviant or spectacular qualities. Their 'in-betweeness,' neither child nor adult, has always been an unsettling position; they do not quite fit and consequently are rendered as a source of concern and in need of strict attention. Similar to media focus on young people, particularly in the postwar era in the Western world, this age-group were either not present or represented in extreme ways and linked with violence, gangs, teenage pregnancy, unemployment, disruption, rebellion, and moral panics. In the mid-twentieth century, scholarship on young people tended to be academically located within psychology, criminology, and education. Psychology investigated social, emotional, and biological development to understand how youth developed into adults and how interventions might keep them on the right track to adulthood. Criminology focused on what appeared to be increasing lawlessness and the so-called 'juvenile delinquency.' Education studies focused on the ways in which young people were not succeeding or were disruptive within the school system, particularly in the case of boys. Hence, the dominant emphasis was generally negative, treating young people as a group to be cured, contained, or coerced into becoming the right kind of members of society. Youth (particularly young males) were studied because they were identified as being abnormal, a problem, or failing.

However, more positive and hopeful social science work with young people began to emerge in the late 1960s and 1970s, and this was particularly strong within the United Kingdom, located at the Center for Contemporary Cultural Studies at the University of Birmingham (Holt, 2009; Skelton and Valentine, 1998). Influenced by Marxism (and later by feminism), scholars focused on youth cultures and the ways in which they were resisting and challenging the social structures and orders that they were growing up in. There was recognition that young people had agency, creativity, and the potential for change within society. It was argued that young people's position within age structures and life courses as 'in-between' or 'on the edge' was what brought about their resistive and inventive activities, cultures, and attitudes. For Marxist and feminist scholars who wanted to identify possibilities for, and work toward social change in the direction of greater equality, youth were seen to hold some of that possibility.

In the 1980s and 1990s social scientists recognized the problematic neglect of young people within their purview, not least because of the important roles they play and will play within society. Key actors in social sciences disciplines began to observe the lack of focus on young people and gather data about their lives in much more of an everyday way, rather than focus solely on the problematic or flamboyant. In 1995 one of the first texts to focus on youth cultures within anthropology was published (Amit-Talai and Wulff); the first book on the geographies of youth appeared in 1998 (Skelton and Valentine); and the highly influential 'International Journal of Youth Studies' was first published in the same year. The international journal of 'Children's Geographies,' with its remit of 'advancing interdisciplinary understanding of younger peoples lives' was launched in 2003 and Nicola Ansell's monograph, 'Children, Youth and Development' appeared in 2005. There were a range of other significant publications within youth studies and cultural studies throughout this time but they are beyond the remit of this article, which will focus specifically on geographies of youth.

Why is making young people visible within the social sciences generally, and its disciplines specifically, important? There are several reasons; here I offer just four that demonstrate the imperative for inclusion. First, it is about justice; no particular social group should be excluded from social science scholarship and the benefits that it can bring. Second, it is about logic; young people make up a significant part of the world's population – in 2000 those aged 0 to 24 years constituted 47.5% of the world's population. If we do not understand their lives, how can we make any claims to knowledge about society? Third, it is about impact; when young people are invisible from study and research they are easier to marginalize and exclude; they are missing from debates, policy making, planning, legislation, and this further deepens their relegation. Fourth, it is about curiosity; what, where, how, and why do young people live their lives differently in relation to other age groups and also within their age grouping? What do these complexities bring to disciplinary approaches?

Geographies of youth emerged as a significant subdiscipline within the broader discipline of geography essentially from the mid-1990s onward. It is strongly influenced by other disciplines and theoretical traditions within the social sciences, such as sociology, cultural studies, feminist theory, youth studies, and social theory and, as it gains critical mass, this geographical work influences other social sciences. A central tenet of the geographies of youth is the focus on specific geographical

 http://dx.doi.org/10.1016/B978-0-08-097086-8.72114-3

concepts, namely place, space, and spatiality, and the ways in which young people interact with their social and physical environments (Evans, 2008). Investigating ways in which young people use places, create spaces, and practice spatialities are central and distinctive aspects of youth geography research and analysis. There remain problems of wider integration, however, as geographies of young people are still relatively absent in the more established subdisciplines of the subject (Skelton, 2010 for analysis of political geography; Skelton and Gough, 2013 for discussion of its absence in urban studies) but this is a changing dynamic as the larger subdisciplines respond to the challenge of previous neglect.

Defining 'Youth' and Why 'Geographies' in the Plural?

Age is a slippery concept and identity. It is mapped onto bodies in different ways in different cultures and geographies. Across the globe, physical bodies are labeled with age and such aged identities come with a sense of what a person should be doing; what they should have achieved; what kinds of legal rights they have; and judgments of appropriate behavior. However, the same age does not mean the same thing in the multitude of societies; age is a relational concept. Nevertheless, in almost all societies there are markers of age upon which social expectations are laid down. There are several rights of passage related to age: first/last day at school; first paid job; first sexual partner; learning to drive; religious rituals such as Confirmation, Bar/Bat Mitzvah, or Ameen; reaching the age of majority; entering a marriage/civil union; parenting a first child; first independent home. Some of these are legally constructed and others are social expectations. Certain rights of passage that may be significant to young people (first love, first sexual encounter, first alcoholic drink, first cigarette, first drive) are often condemned socially and outlawed legally if they take place when the person is too young. Many of these restrictions are based on both protection and/or control of young people. Nevertheless, what is evident is that young people do not go through all of these stages, and that even within the same culture they do not do the same things at the same age (hence the importance of the use of the plural 'geographies'). Indeed globally there seems to have been a slowing down or even complete disruption of youth transitions toward adulthood as they may extend their education, fail to get jobs, be unable to support their own families, and remain dependent on the older generations of their families longer (Jeffrey, 2010; Katz, 2004).

Within most work on geographies of youth, authors will define the age boundaries they are referring to; but these are debated, as are the terms used such as adolescent, teenager, young people, younger people, and youth. The United Nations (UN) also tends to slippage and overlap (Skelton, 2007). 'Youth' are defined as 15 to 24 years old; hence children would be those under 14 years. However the United Nations Convention on the Rights of the Child (UNCRC) defines children as those under 18 years or the age which states identify as the age of majority, which is when, in most cases, children legally become adults (United Nations 'Youth' website). However, youth as a category has considerable valence and while the age of majority throughout most of the world is 18 years, it is clear that young adults still face similar issues to those they faced before they became 18 years. Generally, within geography the definitions adopted for 'youth' include teenagers (13 years plus), which can be qualified as younger or older teens; and 'young people' often relates to ages between 16 and 25 years. There are also geographers who write generically about children and young people at a disciplinary scale but most of their empirical research will involve participants in one group or the other, young people or children. It is important to recognize that there are distinct differences in life experiences, competencies, and agencies between a child of 5 years, a teenager of 15 years, and a young adult of 25 years. Within the generic children's and young people's geographies, concern has been voiced that young people are not as central as children and childhood. In this article and the scholarship it considers, young people are older teenagers and young adults up to the age of 25 years; hence the term 'geographies' of youth.

The term 'geographies,' that is geography in the plural, is deliberately used in this article to remind readers of the intense complexities and contradictions that exist within the concept of youthful geographies. There is considerable diversity of youth experiences in different geographies and these intersect with social identities and differences such as race, ethnicity, gender, sexuality, educational status, bodily abilities, and social class. Early 'geography of youth' tended to be Anglo-American centric, and scholars from, and research in, this region remain predominant in the subdiscipline. However, increasingly, geographies of youth from all over the world are expanding, complicating, and enriching this youthful subdiscipline (Cahill and Katz, 2008; Hansen et al., 2008; Holt, 2011; Jeffrey and Dyson, 2008). The term 'geographies' reminds us of the pluralities of meaning, practices, and constructions of youth and youthhood. This allows the subdiscipline of geographies of youth to challenge Western hegemonic constructions of what is, and who are youth – both within academic geography and also in terms of policies and practices that tend to universalize a singular type of youthhood that emanates from the global North. Some definitions of young people and youth simply do not make sense in different parts of the world. The term 'geographies' reminds us that things are just not that simple and that young people's lives are highly complex, differentiated, and dynamic. This article provides insight into a geographical scholarship that is working to be genuinely international in order to explore beyond, and critique the Anglo-American contexts that have been relatively predominant.

Selected Thematic Research in Geographies of Youth

Despite its relative youthfulness as the 'new kid on the block' in geography, geographies of youth has grown rapidly and developed a varied scholarship that has both theoretical import and provides empirical evidence. This article will, by necessity, have to be selective and will focus on three broad areas of geographical work with a strong focus on young people, specifically those that connect with the more established subdisciplines of political geography (geographies of youthful politics), urban studies (young people and the city), and development studies (young people and development). However, there are other significant focused thematic areas emerging in geographies of

youth (that also often include children). These include young people in relation to public space; social practices and institutions (health, employment, education, training); transport, mobilities, and migration; housing and homelessness; religion; embodiment and intergenerationality; social identities. These identified collectivities are loosely defined, not mutually exclusive nor inclusive of all areas of research; they are listed here in order to provide insight into key thematic areas and spheres of scholarship in youth geographies.

Before I consider the three areas of work where other significant subdisciplines of geography (political, urban, and development geographies) connect with youth geographies, let us briefly consider aspects of a generic geographical focus on young people, i.e., in the context of spaces, places, and scales. Such approaches form the foundation for almost all geographical work on young people.

Young People, Spaces, Places, and Scale

Place, space, scale, and spatialities are central concepts in human geography. 'Where' young people are is a central theme within youth geographies. Their 'whereness,' their spatialities, and the ways in which they make, destroy, and transform spaces and places, have constituted some of the key elements of the subdiscipline; it is all highly geographical. Youth geography work has focused on young people's experiences, behaviors, and practices in the key places of social life: home; school; workplace; streets and open spaces; spaces of leisure, religion, and consumption; virtual space. It has demonstrated the ways in which young people are significant and competent social and spatial actors and agents. There has also been exploration of the spatial–temporal roles that young people play in spaces. City streets, supermarket car-parks, disused buildings, empty rural roads, and parks can be transformed into play-scapes, gang sites, illicit spaces, and/or social spaces by young people at different times of the day and in different seasons. Perhaps the most problematic use of space by young people relates to homeless street youth. There is both anxiety and serious concern over the threat and need that such young people pose (this overlaps considerably with development geographies of youth too). However, for some young people living on the streets, there is an agency and freedom that they resist relinquishing (Bordonaro, 2012).

The concept of scale has been debated in relation to the scalar approach of geographers to young people's lives. Too narrow a focus on the microworlds of young people's everyday worlds in spaces and places extracts them from the wider world context; what then can geographies of young people say about broader issues and how can they contribute to geographical knowledge? Adult practices in society have long closed young people's worlds down with the intention of containing and taming them; some geographical scholarship has pursued a similar approach. An important intervention by Nicola Ansell (2009) has been to reject the notion of scale as hierarchical and to see it, rather, as networked and part of a flat ontology. With such an approach to scale, more complex, accurate, and broader understandings of young people's lives can be garnered. We can examine the ways young people interact and engage with issues, such as politics, changes in education, and unemployment, that transcends scale. Such issues go beyond the local/global binary; they spill out over regional and national boundaries and the consequences touch down in different geographies in different ways. Young people are affected by such issues but they are also part of their creation and transformation, and such activities also transcend scale. Young people migrate to find work or education; they challenge destructive influences and demand improvements; they connect with global movements based within social media. Rethinking scale allows geographers to capture the complexities of young people's geographies as they are lived and practiced beyond the micro-spaces and places they are presumed to reside in.

Young People and Political Geography

Geographical work focusing on young people and politics has tended to lag behind such work in sociology, political sciences, and youth studies but it is currently catching up fast, with special issues and books being published that specifically focus on the geographies of young people's politics (Jeffrey and Dyson, 2008; Kallio and Häkli, 2013; Philo and Smith, 2003 and many more journal articles).

Geographers have begun working with the concept of citizenship, mostly to expand its meaning and hence broaden debates about children's and teenagers' roles in citizenship. In a political–legal rights construct, citizenship is something that those below a certain age cannot make legal claim to; an individual has to reach the age of majority as legally established within the nation state or other legal territory to be recognized as a full citizen. Consequently young people below this age have often been ignored in debates about formal politics (sometimes written as Politics with a capital 'P'); not least because they cannot vote and are not yet part of the electorate. Consequently they are understood not to have any influence in formal politics. Geographers and other social scientists have argued that this is a very limited and limiting approach to citizenship; that in fact, citizenship can be more than a formally recognized political and legal status. Citizenship is bound up with civic duties, social activism, and community care and support. It can be bound up with informal politics (or politics with a small 'p'). There is an expectation of good citizenship in almost all societies and what researchers have shown is that young people play significant roles in citizenship through their care, actions, and social labor for their peers, their families, and their communities, long before they reach the age of legal majority. Throughout the world, young people take responsibilities as citizens of their communities and nations in a range of spaces and ways, regardless of their lack of political–legal status as citizens (Weller, 2007).

Part of the interest in destabilizing the concept of citizenship in order to force a recognition of the citizenship-type energy and action of young people has come about through a vigorous interest in participation. This has some connection to the UNCRC (see below for further discussion), which clearly identified the rights that young people should have to participate in processes and decision-making that affect their lives and those of their communities. Geographers are interested in the ways that young people participate (or don't) and

where and how they demonstrate such participation. Hence work has emerged on school councils, youth parliaments, youth-led resistance, and youthful action around issues such as the right to work, environmental protection, and right to education. Geographers have clearly demonstrated that young people, in many different spaces and places and from different social groups, are participating in their societies in complex and dynamic ways – they are most certainly 'doing' politics. Most of this might be construed as informal politics; but when given the opportunity, young people get involved in the action and responsibilities of formal politics through institutions such as youth parliaments and trade unions.

Young people's political activities within their communities are highly varied in terms of context, motivation, and practices. For some young people of Mexican parentage living on the United States side of the border/la frontera, their politics is about language; and they help their parents engage and connect with social, legal, and political institutions because they translate for them. Some US states have rendered this citizenship-like, political–social, supportive activity illegal, as it can burden the young people or place them in situations they should not be part of at such a young age. However, young people continue to resist the legislation, arguing that they have a right to help their families gain the support they deserve and that they are already exposed to various issues within their communities. Their actions as translators between Spanish and English have therefore become a political and resistive act (see Aitken and Plows, 2010). In other communities, young people seek paid employment in all manner of ways to contribute to their families, especially at times of economic crisis. This can bring them into conflict with legislation against underage labor, but throughout the world, many young workers are forming international, working-youth organizations in order to make their case not only for the right to work but also their right to protection as workers. Young people also demonstrate political action and responsibility to challenge social injustice, and set up or get involved in action and community groups against violence, racism, homophobia, sexism, and abuse, for example. Activities related to such political deeds take place somewhere, whether in public space, within institutions such as schools and youth groups, and/or through social media; geographers are therefore alert to the ways in which spaces and places play significant roles in the structure, temporality, and spatiality of such exploits of youthful politics.

Geographical scholarship about young people's politics has made young people's actual and potential political agency, subjectivity, competence, and capacity visible. Geographers have demonstrated the variety of ways, in an assortment of geographies, in which young people are being political and doing politics in order to create change. Geographies of youthful politics are important aspects of political processes and increasingly, the more well-established subdiscipline of political geography is slowly coming to realize that young people have a role to play. When young people come into the remit of political geography they force a rethinking of the foundational concepts and definitions of the subdiscipline, because young people often do politics differently from adults. It is also, as noted above, about social justice. Young people face marginalization and exclusion within the political arena and consequently geographers and geography work to expose such omissions and write young people's political geographies into geographical and social sciences scholarship (Skelton, 2013b).

Young People and Urban Geography

Over half of the world's young people live in urban places and so they are in and of the city; they experience the city, and they are part of making the city. Young urbanites are important actors in all aspects of urban dwelling and, in turn, their own lives are shaped, influenced, supported, and thwarted by city processes and spatial politics, such as segregation, provision, facilities, and neglect. It is important to understand the mechanisms and processes (economic, political, cultural, and social) through which young people are marginalized, excluded, or included as residents of the city; as well as to consider the ways in which young people resist and rework urban inequalities to improve their city lives (Hörschelmann and van Blerk, 2012). Young people are often the most entrepreneurial, creative, and energetic members of their communities. The city is the site of possibility for their inventiveness, which might be related to finding sources of income (vending on the streets); creating designs and entertainment (street art or busking); hustling for jobs; or learning from artisan workers by watching and copying. Greater political and financial investment directed toward urban youth should be an important component of urban planning and policy; in reality this age group is the most neglected.

Geographers have shown that young people use the city in very different ways to adults. Young people are everywhere present in the city despite attempts by planners and policy actors to plan them out of public and commercial spaces; contain them in age-specific institutions; and exclude them from spaces designed for adults. From skateboarding to cycling and from parkour to playing, young people make use of urban spaces in almost impossible, unimagined, yet inventive ways, as countless YouTube videos of stunt cyclists and parkour groups demonstrate (YouTube links 1 and 2). In the city, young people enter places where they are not supposed to be and use spaces in ways that planners and architects could never have predicted. Such adaptability and audacity often brings young people into conflict with other users of the city and also urban authorities, notably security guards and the police. In more progressive and youth-friendly cities, such activities can be a starting point of greater inclusion and participation in planning and creating spaces for young people in the urban landscape, for example, as in Curitiba, Brazil.

In response and as a challenge to the apparent Western-centric approaches to geographies of young people in the city, Hansen et al. (2008) provide an interdisciplinary analysis of life in cities of the South, notably Recife in Brazil, Hanoi in Vietnam, and Lusaka in Zambia. Partly this is about redressing a scholarly imbalance but it is also about the demographics and processes of urban spaces and urbanization in these continents. Whereas Northern/Western cities are experiencing an aging population as older people make up more and more of the population, in Southern cities young people are the growing population and this has significant cultural, political, and socioeconomic impacts and consequences. Hansen et al.

demonstrate that while there are similarities between the young people in Latin-American, sub-Saharan African, and South East Asian cities, and young people in Western cities, particular configurations and geographical relations of history, global processes, economic and political structures, cultural practices, and urban planning, create uncertainties, fears, and hardships of particular intensity in Southern cities. What constitutes suitable or possible transitions for young people; how adulthood is defined and recognized; and what resources exist to support young people varies enormously between cities of the South and the West; between cities within the South; and within different parts of individual cities.

What perhaps is distinctive in the current era is that urban young people in different parts of the world probably know more about the lives of urban youth in other parts of the world than ever before, because of global media, social on-line media, and for some groups, increased mobility and access to international travel. Some of that knowledge, particularly knowledge relating to travel, is particularly one-way, as privileged Western youth take their 'gap years' between school and university to travel, often to cities of the world much poorer than their own. For young people of the South their mobilities may take them to the West but for very different reasons, most notably migration for work or study, legally or illegally. Others may arrive in the West as refugees or asylum seekers, literally moving for their lives. Many young migrants or refugees may be surprised and disappointed to find themselves only able to work and reside in the poorest parts of Western cities, not so very different from their home cities.

Mobilities and immobilities within cities is an area of geographical research that has demonstrated that not only do young people use the city in different ways, but they also move into, out of, and through the city in different ways to adults. Additionally mobilities and immobilities are differentiated between groups of young people, notably in relation to gender, race, and socioeconomic status. Skelton (2013a) demonstrates that in a city like Auckland where cars are relatively cheap and the city is designed for the car user, young people with wealthy parents can gain access to, or own, cars from the age of 17. They experience considerable independent mobility within the city but tend to use their cars to travel to places they know and to engage with people of the same educational and socioeconomic class. On the other hand, young Pasifika people have the lowest rates of car access and rely heavily on public transport (a relatively expensive and scarce commodity in Auckland). They tend to walk a lot in their neighborhoods to see their friends. They too spend time in places they are familiar with and in the company of other islander youth, but these spatialities of socioeconomic status are very different from each other. However, some young people use the transport possibilities in order to explore different parts of their city deliberately, to see what other places are like and with the hope of encounters with people different from themselves; this was particularly true of young women. With friends, some wealthier girls used their cars to escape the sameness of the neighborhood and traveled to other parts of the city for leisure and excitement; poorer Pasifika girls used buses and trains to explore the downtown sites of the marina areas and Queenstreet, with their bars and restaurants, high-end shops, and municipal facilities such as art galleries. Consequently these girls cross urban, social, and cultural boundaries in order to make use of the city and to learn more about other spaces, places, and people. Such mobility can be an important part of developing an urban cultural capital that may enhance their future training and employment opportunities, as they develop confidence in and about the city and what it might have to offer. This demonstrates the ways in which race, gender, and socioeconomic status intersect in young people's lives in ways that directly affect how they access and utilize the urban spaces they dwell in (see Reynolds, 2013; Allen and Hollingworth, 2013 for examples of ethnic identity, social capital, and immobility/mobility in the United Kingdom).

Young People and Development Geography

Geographers have made significant interventions and contributions to placing young people in development geography and wider development studies and agendas, as well as contributing to actual development policy and practice. A focus on young people (and children), within geography, is not just about social justice or the possibilities for intellectual challenges to established conceptualizations of development; it is also about very practical factors, such as numbers and where young people are. Third World countries (also known as the 'majority world,' and 'lesser developed countries') account for 90% of 0–17 year olds and 85% of 15–24 year olds (Ansell, 2005). Hence the majority of the world's young people live in so-called 'developing contexts' and it is inevitable that they play important roles in development processes and practices.

Initially, work focused on the adding of young people (and children) into development studies perspectives; it was about making young people visible within development discourse and practice. More recently, geographers have raised the importance of concomitant rethinking of economic development that places the West as central, and of stage-assumptive child development that places adults as central (Aitken et al., 2008). In more practice and policy contexts, development geographers continue to recognize the complexities and often very deleterious effects, of major problems such as poverty, natural hazards, or state/civil violence in young people's lives. Particularly influential work has been done around HIV/AIDS development work where social reproductive responsibilities, burdens of care, household maintenance, and livelihoods have fallen on the shoulders of young people, in the absence of adult family members due to ill health or death (van Blerk and Ansell, 2007).

Other development issues have included the ways in which young people are victims of violence, particularly state violence and civil war, including the associated forced mobility of refugees. Development geographers have been alert to the ways in which young bodies have been commoditized as laborers, sex workers, and/or trafficked people. Young people, especially young men, have been recognized as perpetrators (as well as victims) of youth violence and creators of social anxieties relating to the formation of gangs and their powerful abilities to create disruption and social fear (Jones, 2008). Work with, and about, young people in a development context has allowed insights into the ways in which global processes – globalization, neo-liberalism, international debt, privatization, structural adjustment, securitization, international agreements, war,

forced migration – touch down into and damage young lives in extreme ways. All of these processes have implications for their productive social and economic capacities in the future. There are also cases where global processes, particularly those with a more social justice imperative such as some development approaches and NGO work, facilitate and enhance young people's resilience and ability to rework their lives into something positive and possible.

Increasingly, and particularly in the decades since the launch of the UNCRC in 1989, the participation of young people in processes and decisions that affect their lives has been encouraged alongside the more established international agreements around provision and protection. Partly through this influence and partly through new academic and political thinking, young people have been recognized as actors and agents within development in their own right; they are progressively seen as part of the sociospatial processes at play, rather than being perceived as passive recipients. However, it is important to resist the universalization tendency based on neoliberal individualism that has emerged through the UNCRC and to bear in mind that not all young people's lives are the same, between and within different geographies. Consequently, young people will have variable access to resources and differential potential to develop various capacities to achieve what they believe to be best for them in their lives and for their communities. Nevertheless the recognition of young people as development agents has been an important shift in approach for development geographers. It is not so much about making the world better for the next generation but about working with current generations to make the world better for now; it is also about not imposing adult agendas on young lives – this is part of adulthood. Young people make important contributions within development and this has to be recognized and worked with. Geographers within development studies have risen to this task through their work with young people.

Conclusion

Youth geographies is an exciting subdisciplinary area of geography and connects across much of the social sciences. Youth geographies also refers to the lived geographies and spatialities of young people in space and place. Young people are increasingly being recognized as, and have for some time been performing the roles of agents within contexts of politics, cities, and development (along with other aspects of everyday life). It has taken time for the academics to catch up and explore further what young people do, where they are, and how they live. Fortunately for young people themselves, their families, and their communities, young people have been living, doing, and being geographically active always.

Abstract

We present evidence showing that in advanced countries there has been a rise in both youth unemployment, a decline in youth employment, alongside as a rise in underemployment for those youngsters lucky enough to have a job. We also document marked differences across countries in the size of the youth cohort, which in most western countries rose by around 10% between 2000 and 2010 but is then set to decline sharply. We examine youth wages and discuss evidence that suggests that long spells of unemployment create permanent scars.

Across most OECD countries, young people were especially hard hit by the onset of the Great Recession. (The OECD has a major program on youth unemployment; see http://www.oecd.org/youth.htm. See also its Jobs for Youth Review http://www.oecd.org/employment/theoecdjobsforyouthreview.htm with reports on youth labor markets in 16 countries – Australia, Belgium, Canada, Denmark, France, Greece, Japan, Korea, the Netherlands, New Zealand, Norway, Poland, the Slovak Republic, Spain, the United Kingdom, and the United States. See also ILO (2013) and work at the European Commission – 'Youth employment,' http://ec.europa.eu/social/main.jsp?catId=1036.) This was consistent with the predictions of the existing literature, which suggested that youth unemployment rates are more cyclically volatile than adult rates, and so it turned out. The definitive work on youth unemployment is contained in three National Bureau of Economic Research (NBER) volumes that documented the struggles the young experienced during downturns (Freeman and Wise, 1982a; Freeman and Holzer, 1986; Blanchflower and Freeman, 2000). In a series of earlier papers, we have updated this work to examine the youth unemployment problem in the Great Recession across countries (Bell and Blanchflower, 2011a,b,c), as well as other work on overall unemployment (Bell and Blanchflower, 2010a,b). This article builds on that work.

Of note is the fact that during the Great Recession, youth unemployment has been a major issue in the Southern European countries, especially Greece, Italy, Portugal, and Spain (Dolado et al., 2013; Eichhorst and Neder, 2014), but also in France, the UK, and Sweden. It has been much less of a problem in Germany, Austria, and the Netherlands. (For recent work on youth unemployment in France and Germany, see Cahuc et al. (2013); on Germany, see Rinne and Zimmermann (2012); and Bell and Blanchflower (2014) for Greece.) First, we set out the recent facts and then we turn to the findings from the literature. We show that, in advanced countries there has been a rise in both youth unemployment, a decline in youth employment, alongside as a rise in underemployment for those youngsters lucky enough to have a job. In developing countries, youths have generally fared much better. We also document marked differences across countries in the size of the youth cohort, which in most Western countries rose by around 10% between 2000 and 2010, but is then set to decline by around 20% by 2020. In contrast, countries in Eastern Europe saw declines of around a quarter in the number of young people between 2000 and 2010; by 2020, their numbers are expected to have declined by two-fifths. In further contradistinction, the cohort size among North African countries will have risen by a third.

The Recent Evidence

Table 1 presents the most recent data we have available on youth unemployment rates, here defined as being for those under the age of 25. It is apparent, as noted above, that they are especially high in Southern Europe, with over half of the youth workforce unemployed in Spain (54%) and Greece (53%), but also very high in Italy (43%) and Croatia (42%), and averaging 22% in the EU and 23% in the Euro Area. We also present unemployment rates for older adults and in the final column the ratio of the two. The United States has a relatively low youth unemployment rate of 13% well below that of Europe (22%), although the ratio compared to the older age group is about the same – 2.7 and 2.4 – respectively. Interestingly, the four countries with the highest ratios around four – Romania; Sweden, Italy, and the UK – are not those with the highest rates of youth unemployment. The concern is that high relative rates might be a problem when youth compare themselves to adults, given we know from happiness research that relative things matter (Luttmer, 2005). It is instructive that there have been riots in both the UK and Sweden. (In May 2013, there were riots in the suburbs of Stockholm, apparently stoked by long-term unemployment, http://www.theguardian.com/world/2013/may/23/swedish-riots-stockholm and riots in London, which spread to other UK cities in the summer of 2011 http://www.theguardian.com/uk/series/reading-the-riots.) **Figure 1** reports time series of youth–adult unemployment rates for four countries with high ratios – Italy, Sweden, and the UK with the United States plotted for comparison purposes. The extremely high ratio of around seven is especially notable in Italy, along with its subsequent decline, whereas the UK and Sweden saw a steady increase, which was not seen in the United States.

Figure 1 Ratio of youth–adult unemployment rates, 1983–2014 (Italy, Sweden, the United States, and the UK).

Table 2 reports on levels of youth employment to population rates, which can be a more accurate indicator of youth joblessness than unemployment rates, given low levels of youth participation rates in some countries, which are also reported in the table, for 2008 and 2013. The higher the proportion of youngsters in education, the lower will be the participation rate.

It turns out that we get a very similar picture of youth joblessness from the employment rates as we do from unemployment rates. Employment rates for the young fell during the recession in most advanced countries and are lower in 2013 than they were in 2008; the three main exceptions are Sweden, Switzerland, and Germany where they are unchanged. In contrast, employment rates are higher in Chile, Columbia, Israel, and Turkey. Among advanced countries, participation rates of the young are only up in Switzerland (+7ppt); Sweden (+1ppt), suggesting that the young have not rushed to increasingly expensive education as a refuge from joblessness.

So in most European countries, both employment and participation rates are down since the onset of recession for the young and some sharply so. Examples of the differences between 2008 and 2013 rates for some selected countries with participation rates with employment rates in parentheses are as follows as percentage points: Denmark −10 (−12); Canada −4 (−5); the UK −4 (−7); the United States −4 (−5); Germany −2 (0); Finland −5 (−6); Spain −10 (−21); Ireland −13 (−18); France 0 (−2); Portugal −6 (−12); Italy −1 (−6); and Greece −2 (−12). It turns out that the three countries with the highest employment rates are also the ones with the highest participation rates – Iceland, the Netherlands, and Switzerland. The correlation coefficient is 0.96. The three countries with the lowest employment rates – Italy, South Africa, and Greece are close to the bottom in the ranking of participation rates, ranking 33, 38, and 34, respectively. As a consequence, unemployment rates are also up in the advanced countries but less so in the developing world.

A phenomenon that we have also observed in the recession is that not only those without jobs, the jobless, have been impacted, but also the youngsters who have held jobs. Table 3 shows the rise in the share of involuntary part-time employment in total employment of the young, which has more than doubled in many countries since including Greece, Portugal, the Netherlands, the UK, the United States, and especially Spain that has seen nearly a threefold increase. Young workers are disproportionately underemployed (Bell and Blanchflower, 2011c).

These rises in unemployment, and falls in employment and participation rates that have occurred in many countries have come at a time of large youth cohorts. So, a rise in the supply of young people may exacerbate further the evidence found by Kahn (2011) that graduating from college in a recession permanently lowers a cohort's earnings. Table 4 reports on such changes in cohort size for a number of countries since 2000 and reports the change in the size compared with that in 2000 over the period 2004–2020. We can calculate 16–24 cohort size in 2020 by extrapolating from the number of 6- to 14-year-olds 10 years earlier, assuming no further immigration, which is a stretch of course. It is apparent that some countries had big increases in the size of their youth cohorts between 2000 and

Table 1 Youth and adult unemployment rates, 2014 ranked by youth unemployment rates

2008 when the Great Recession started, including the UK, Sweden, and the United States, whose cohort size was 10% bigger. In contrast, cohort size was sharply smaller in Spain (−30%), Italy (−21%), and Greece (−25%). By 2020, youth cohort size will be at least 10% smaller in most countries except the United States, where it will continue to grow. By 2020, the youth populations of North Africa and Latin America will have grown by over a quarter, whereas that of Western Europe will have shrunk by 10%. The youth population in most East European countries, including Poland and Russia, will likely fall by around two-fifths over a 20-year period from 2000 to 2020. The Arab Spring occurred in countries that had growing youth cohorts and high youth unemployment rates.

We now turn to examine five questions about youth unemployment from the literature. The concern is that spells of unemployment experienced during the Great Recession will create permanent scars for a *Lost Generation*.

The Literature on Youth Joblessness

There is a large literature on youth unemployment, drawing on the experience of recent decades. In this section, we examine this literature and attempt to answer eight vital questions regarding the workings of the youth labor market and the consequences of failing to successfully make the transition from school to work.

Is Youth Unemployment Cyclical or Structural?

Clark and Summers (1982), in their classic study of the dynamics of youth joblessness, argue that the problem of teenage unemployment arises from a shortage of jobs. "Aggregate demand has a potent impact on the job prospects and market experience of teenagers" (1982: p. 230). Freeman and Wise (1982b), for example, found in their study of youth

joblessness in the 1970s that it was concentrated, by and large, among a small group who lacked work for extended periods of time. Over half of the male-teenage unemployment they examined was among those who were out of work for over 6 months, a group constituting less than 10% of the youth labor force and only 7% of the youth population. Freeman and Wise reported that the youths who make up the relatively small group that was chronically without work had distinctive characteristics. They were disproportionately black, disproportionately high-school dropouts, and disproportionately residents of deprived areas.

Blanchflower and Freeman (2000) identified one basic pattern in the job market for young workers: the disproportionately large response of youth employment or unemployment to changes in overall unemployment. They argued that the sensitivity of youth employment and unemployment to the overall rate of unemployment dominate sizable demographic and structural changes favorable to youth in determining how youths fare in the job market. OECD (2008) confirmed this conclusion "Youth unemployment rates are more sensitive to business-cycle conditions than the adult unemployment rate and this high-sensitivity tends to decline progressively with age." Consistent with this argument, there is evidence that young people do well in booms. Freeman and Rodgers (2000) analyzed the 1990s boom in the United States and found that it substantially improved the position of noncollege-educated young men, especially young African-Americans who are the most disadvantaged and troubled group in the United States. Young men in tight labor markets experienced a substantial boost in both employment and earnings. Adult men had no gains and their earnings barely changed even in areas where unemployment rates were below 4%.

There is also evidence of state dependence in youth unemployment. In this context, state dependence means that the experience of one spell of unemployment of itself increases the probability of further spells. This may be because on the demand side, employers are less willing to hire those with a record of unemployment or that, on the supply side, the experience of unemployment discourages individuals from job search activity.

How Has Changed School Enrollment Impacted on Youth Unemployment?

Most OECD countries have tried to extend the duration of formal schooling in recent decades. This delays entrance into full-time employment, but not necessarily part-time work. Table 5

Source: OECD Education at a Glance 2012 Highlights.

shows there are marked variations in the proportion of young people who are students. This ranges from a high of 96% in Ireland for 15- to 19-year-olds to a low of 54% in Mexico, and a high of 42% for 20- to 29-year-olds in Finland compared to a low of 13% in Luxembourg. These levels reflect a belief in most industrial countries that greater investment in human capital is required to maintain competitiveness, but they may also reflect lowering costs of education as average family sizes fall. Yet again, it may be a defensive strategy, with enrollment increasing when the labor market deteriorates. It is especially notable in the Table 5 that the rise in the proportions of young people who are students as a response to youth joblessness especially in Greece among 20- to 29-year-olds, that Bell and Blanchflower (2014) found were especially impacted by a lack of jobs. The rise in attendance rates across countries is much more marked among 20- to 29-year-olds, partly because of the already high rates existing for the younger group. Rates are up by at least 3% points, between 2008 and 2010, for 20- to 29-year-olds in Austria, Germany, Greece, Iceland, Ireland, Luxembourg, Spain, Sweden, and the United States.

Increased schooling affects youth unemployment in two ways. First, so long as increased educational attainment is increasing the 'employability' of the young, it should increase the success rate of their job search activity. On the other hand, delayed job market entry caused by additional schooling may reduce the average 'employability' of those that are economically active, since those selected into additional schooling are likely to be more able. This effect may be difficult to disentangle within aggregate statistics, since some of those taking additional schooling may also be economically active and therefore classified as either employed or unemployed.

Have Youth Wages Been Too High, so Increasing Youth Unemployment?

There appears to have been a secular decline from the early part of this century in relative youth wages, some recovery around 2007–08 followed by further decline during the recession. Employment among older workers has increased during the recession, even though these data suggest that their relative wages have been increasing compared with those of young people in the UK and the United States. There is no prima facie evidence of younger workers pricing themselves out of jobs.

To examine this further, we looked at microwage data for the United States and the UK to see how the relative wages of the young had changed over the recession. For the UK we took Labour Force Survey (LFS), while for the United States we have data from the Merged Outgoing Rotation Group (MORG) files of the Current Population Survey (CPS). For both countries, we have hourly earnings data since 2001 and can compare the earnings of youngsters – we present data for 16 to 19, 20 to 24, and 25- to 29-year-olds – to earnings of prime-age workers aged 40–44 for 2001, 2004, 2008, and 2013. Interestingly, the ratios and the changes are broadly similar across the two countries.

	2001	*2004*	*2008*	*2013*
The United Kingdom				
16–19/40–44	41%	41%	37%	36%
20–24/40–44	61%	60%	53%	52%
25–29/40–44	84%	84%	74%	70%
The United States				
16–19/40–44	41%	40%	38%	37%
20–24/40–44	56%	54%	53%	49%
25–29/40–44	80%	77%	76%	73%

We find a big decline in the ratio of youth in each of the three categories post-2004. In the United States, the 16- to 19-year-olds earn 37% (36%) compared to 41% (41%) in 2001, whereas the 25- to 29-year-olds had a bigger absolute decline from 80% (84%) in 2001 to 73% (70%) with the UK numbers in parentheses. For both the UK and the United States, it appears that youth wages have been flexible downward in the face of declining labor demand.

Do Active Labor Market Programs Work? (Hint: No!)

In response to the substantial increases in youth unemployment during the 1980s and early 1990s, there was a significant increase in policy initiatives targeted at unemployment in

general and youth unemployment in particular. These culminated in the OECD Jobs Study (1994), which argued that policies to improve the working of the labor market were critical for reducing high levels of youth unemployment. It suggested that:

> A progressive shift of resources is needed from passive income support to active measures. Active labor market policies improve access to the labor market and jobs; develop job-related skills; and promote more efficient labor markets.
>
> OECD Jobs Study, 1994

With OECD encouragement, many member countries introduced a range of active labor market policies (ALMPs). These were extensively evaluated to determine their labor market effects. Card et al. (2009) carry out a meta-analysis of ALMPs. They examined 199 programs drawn from 97 studies over the period 1995–2007. The programs themselves are heterogeneous covering classroom and work experience, job search assistance, subsidized public and private employment programs. In the short run, the number of programs with a significantly positive outcome only exceeds those with a significantly negative outcome by a small margin. Over longer time horizons, the balance is more in favor of positive outcomes.

There are also significant differences between countries in the types of programs, which succeed or fail. There is no upward trend over time in positive outcomes. The evaluations contain little information on costs, making it difficult to establish how affordable large-scale expansion of successful programs might be. The Card et al. study supports Grubb and Martin's (OECD, 2001) conclusion that, "one of the most disappointing conclusions from the evaluation literature is that almost all evaluations show that special measures are not effective for disadvantaged youths." There is very little evidence from around the world that ALMPs work well in recessions.

What Impact Does Youth Unemployment Have?

There is a wealth of literature showing that unemployment is a stressful life event that directly reduces individual well-being. This applies not just to the unemployed, but also may affect the employed due to increased anxiety over job security. Unemployment increases susceptibility to malnutrition, illness, mental stress, and loss of self-esteem, and increases the risk of depression. The unemployed also appear to be at higher risk of committing suicide and of poor physical health outcomes later in life. Low levels of happiness and health have predictive power for subsequent outcomes (Blanchflower, 2009).

Youth unemployment also has particularly adverse social impacts. Higher unemployment is associated with increases in burglaries, thefts, and drug offenses. Unemployment is often part of the cycle where involvement in crime reduces subsequent employment prospects and consequently increases the probability of participating in crime. There is new evidence that even young people who choose to go to college or university are hurt if they enter the labor market during a recession. Kahn (2010) has shown that graduating from college during a recession has large, negative, and *persistent* effects on wages. Lifetime earnings are substantially lower than they would have been if the graduate had entered the labor market in good times. Furthermore, cohorts who graduate in worse national economies tend to end up in lower-level occupations. Giuliano and Spilimbergo (2014) suggest that the period of early adulthood (between 18 and 25) seems to be the age range during which people are more sensitive to macroeconomic conditions. They find that being exposed to a recession before age 17 or after age 25 has no impact on beliefs about life chances. However, youngsters growing up during recessions tend to believe that success in life depends more on luck than on effort; they support more government redistribution, but have less confidence in public institutions. Recessions seem to adversely affect youngsters' beliefs.

Further, unemployment while young, especially of long duration, appears to be associated with permanent scars rather than the temporary blemishes that result for older workers (Ellwood, 1982). The majority of older workers get over spells of unemployment reasonably quickly while youngsters do not as they struggle to find a toehold in the labor market. The scarring effect of youth unemployment has two components: first, for the young, a spell of unemployment does not end with that spell; it raises the probability of being unemployed in later years. Second, early spells of unemployment also carry a wage penalty. These effects are much larger than for older people experiencing unemployment. Mroz and Savage (2006) find that a 6-month spell of unemployment at age 22 results in an 8% lower wage at 23 and even at ages 30 and 31, wages are 2–3% lower than they otherwise would have been.

In Bell and Blanchflower (2011a), we found that early adulthood unemployment in the UK creates long-lasting scars, which affect both wages and happiness. Our results showed significant effects at the age of 50 from early adulthood unemployment, but none from recent unemployment experience. Bell and Blanchflower (2011b) extended that work and found evidence that spells of youth unemployment have harmful impacts on a number of outcomes, including health and job satisfaction, many years later. A spell of unemployment when young continues to have a negative impact in later life. Our evidence is consistent with the view that negative impacts on wages, life satisfaction, health and job satisfaction may persist well into the future.

Conclusions

The young have taken it on the nose in the Great Recession in most European countries and especially so in Southern Europe where youth joblessness has soared. This has not been true everywhere though; the young have done well both absolutely and relatively in Germany and Austria where youth unemployment rates have remained in single digits. Relative rates have been high in a number of other countries including the UK and Sweden where we have observed serious social disorder and riots. The consequence of these high rates of joblessness is that many youngsters have not been able to strike out on their own. This has meant that there has been a marked rise since 2008 in the proportion of youngsters who continue to live with their parents even into their late-twenties.

Youth unemployment rates are highly cyclical so the likelihood is that as economies recover on average, the young will be the ones who benefit the most having lost the most in the downturn. But there will be losers. We have also found that the young are faced with a double whammy, when they have jobs they tend to be underemployed. They are also more likely to be in a part-time job when they would like a full-time job. We have also found evidence that their earnings relative to adults has also fallen since the Great Recession started.

The biggest concern is that there is evidence that permanent scarring can occur when young people experience long spells of unemployment and are unable to make a foothold in the labor market. The concern is that these young people may end up as a lost generation and then it is too late.

This article is a revision of the previous edition article by M.M. Braungart, volume 24, pp. 16668–16671, © 2001, Elsevier Ltd.

Abstract

These are amorphous, multicentered movements among young people who regard themselves, and are regarded by others, as an upcoming, usurping generation. Such movements are likely to form in periods of major historical change. This article discusses the main youth movements that have been formed during and since the midtwentieth century: the student movements of the 1960s and the 1970s; movements that challenged colonial and neocolonial rulers in less-developed countries; young people's involvement in the revolutions that saw the end of communism in East-Central and South-East Europe in 1989, and in the subsequent 'color revolutions' in some former Soviet republics; the still evolving movements that resist neoliberalism and its impacts (*Anti-Globalisation*, the *Indignados*, *Occupy*); and the *Arab Spring* of 2011. It is concluded that youth movements are most successful in mobilizing dissent while they lack clear aims and leaders; that while they retain the support of security services, incumbent political elites can usually resist these challenges; and that youth movements are liable to fragment when they begin to engage in conventional democratic politics.

Definitions and Theoretical Approaches
